# Chapter 1

## Introduction

### 1.1 Course Structure

Dr Azelea Raad

Dr Herbert Wiklicky

#### First Half

- The while language
- Big & small step semantics
- Structural induction

#### Second Half

- Register Machines & gadgets
- Turing Machines
- Lambda Calculus

### 1.2 Algorithms

#### Euclid's Algorithm

#### Extra Fun! 1.2.1

Algorithm to find the greatest common divisor published by greek mathematician Euclid in  $\approx 300$  B.C.

```
-- continually take the modulus and compare until the modulus is zero
euclidGCD :: Int -> Int -> Int
euclidGCD a b
| b == 0 = a
| otherwise = euclidGCD b (a `mod` b)
```

#### Sieve of Eratosthenes

#### Extra Fun! 1.2.2

Used to find the prime numbers within a limit. Done by starting from the 2, adding the number to the primes, marking all multiples as non-prime, then repeating progressing to the next non-marked number (a prime) and repeating.

The sieve is attributed to Eratosthenes of Cyrene and was first published  $\approx 200$  B.C.

```
-- Filtering rather than marking elements
eraSieve :: Int -> [Int]
eraSieve lim = eraSieveHelper [2..lim]
where
  eraSieveHelper :: [Int] -> [Int]
```

```

eraSieveHelper (x:xs) = x:eraSieveHelper (filter (\n -> n `mod` x /= 0) xs)
eraSieveHelper [] = []

```

## Al-Khwarizmi

## Extra Fun! 1.2.3

A persian polymath who first presented systematic solutions to linear and quadratic equations (by completing the square). He pioneered the treatment of algebra as an independent discipline within mathematics and introduced foundational methods such as the notion of balancing & reducing equal equations (e.g subtract/-cancel the same algebraic term from both sides of an equation)

His book title *الجبر* "al-jabr" resulted in the word *algebra* and subsequently algorithm.

Algorithms predate the computer, and have been studied in a mathematical/logical context for centuries.

- Very early attempts such as the Antikythera Mechanism (an analogue calculator for determining astronomical positions)  $\approx 100$  B.C.
- Simple configurable machines (e.g automatic looms, pianola, census tabulating machines) invented in the 1800s.
- Basic calculation devices such as Charles Babbage's *Difference Engine* further generalised the idea of a calculating machine with a sequence of operations, and rudimentary memory store.
- Babbage's Analytical Engine is generally considered the world's first digital computer design, but was not fully implemented due to the limits of precision engineering at the time.
- English mathematician Ada Lovelace writes the first ever computer program (to calculate bernoulli numbers) on Babbage's analytical engine.

## Note G

## Extra Fun! 1.2.4

While translating a french transcript of a lecture given by Charles Babbage at the University of Turin on his analytical engine, Ada Lovelace added several notes (A-G), with the last including a description of an algorithm to compute the Bernoulli numbers.

Number of Operation.	Nature of Operation.	Variables acted upon.	Variables receiving results.	Indication of change in the value of any Variable.	Statement of Results.	Data.	Working Variables.										Result Variables.				
							$v_{V_1}$	$v_{V_2}$	$v_{V_3}$	$v_{V_4}$	$v_{V_5}$	$v_{V_6}$	$v_{V_7}$	$v_{V_8}$	$v_{V_9}$	$v_{V_{10}}$	$v_{V_{11}}$	$v_{V_{12}}$	$v_{V_{13}}$	$v_{V_{14}}$

Here follows a repetition of Operations thirteen to twenty-three.

This is the known example of a computer program.

The *Difference Engine* was used as the basis for designing the fully programmable *Analytical Engine*.

- Held back by lack of funds, limitations of precision machining at the time.
- Contains an ALU for arithmetic operations, supports conditional branches and has a memory
- Part of the machine (including a printing mechanism) are on display at the science museum.

## 1.3 Decision Problems

### Formulas

### Definition 1.3.1

Well formed logical statements that are a sequence of symbols form a given formal language. e.g  $(p \vee q) \wedge i$  is a formula, but  $) \vee \wedge ji$  is not.

Given:

- A set  $S$  of finite data structures of some kind (e.g formulae in first order logic).
- A property  $P$  of elements of  $S$  (e.g the property of a formula that it has a proof).

The associated decision procedure is:

Find an algorithm such that for any  $s \in S$ , if  $s$  has property  $P$  the algorithm terminates with 1, otherwise with 0.

### 1.3.1 Hilbert's Entscheidungsproblem

*Is there an algorithm which can take any statement in first-order logic, and determine in a finite number of steps if the statement is provable?*

### First Order Logic/Predicate Logic

### Definition 1.3.2

An extension of propositional logic that includes quantifiers ( $\forall, \exists$ ), equality, function symbols (e.g  $\times, \div, +, -$ ) and structured formulas (predicate functions).

This problem was originally presented in a more ambiguous form, using a logic system more powerful than first-order logic.

'Entscheidungsproblem' means 'decision problem'

Many tried to solve the problem, without success. One strategy was to try and disprove that such an algorithm can exist. In order to answer this question properly a formal definition of algorithm was required.

## 1.4 Algorithms

### 1.4.1 Algorithms Informally

Common features of Algorithms:

<b>Finite</b>	Description of the procedure in terms of elementary operations.
<b>Deterministic</b>	If there is a next step, it is uniquely determined - that is on the same data, the same steps will be made.
<b>Terminate?</b>	Procedure may not terminate on some input data, however we can recognize when it terminates and what the result is.

In 1935/36, Alan Turing (Cambridge) and Church (Princeton) independently gave negative solutions to Hilbert's Entscheidungsproblem (showed such an algorithm could not exist).

1. They gave concrete/precise definitions of what algorithms are (Turing Machines & Lambda Calculus).
2. They regarded algorithms as data, on which other algorithms could act.

- They reduced the problem to the *Halting problem*.

This work led to the Church-Turing Thesis, that shows everything computable is computed by a Turing Machine. Church's Thesis extended this to show that General Recursive Functions were the same type as those expressed by lambda calculus, and Turing showed that lambda calculus and the turning machine were equivalent.

### Algorithms Formalised

Any formal definition of an algorithm should be:

- Precise** No ambiguities, no implicit assumptions, Should be phrased mathematically.
- Simple** No unnecessary details, only the few axioms required. Makes it easier to reason about.
- General** So all algorithms and types of algorithms are covered.

### 1.4.2 The Halting Problem

The *Halting problem* is a *decision problem* with:

- The set of all pairs  $(A, D)$  such that  $A$  is an algorithm, and  $D$  is some input datum on which the algorithm operates.
- The property  $A(D) \downarrow$  holds for  $(A, D) \in S$  if algorithm  $A$  when applied to  $D$  eventually produces a result (halts).

Turing and Church showed that there is no algorithm such that:

$$\forall (A, D) \in S \left[ H(A, D) = \begin{cases} 1 & A(D) \downarrow \\ 0 & \text{otherwise} \end{cases} \right]$$

The final step for Turing/Church's proof was to construct an algorithm encoding instances  $(A, D)$  of the halting problem as statements such that:

$$\Phi_{A,D} \text{ is provable} \leftrightarrow A(D) \downarrow$$

### 1.4.3 Algorithms as Functions

It is possible to give a mathematical description of a computable function as a special function between special sets.

In the 1960s Strachey & Scott (Oxford) introduced *denotational semantics*, which describes the meaning (denotation) of an algorithm as a function that maps input to output.

#### Domains

#### Definition 1.4.1

Domains are special kinds of partially ordered sets. Partial orders meaning there is an order of elements in the set, but not every element is comparable.

Partial orders are reflexive, transitive and anti-symmetric. You can easily represent them on a Hasse Diagram.

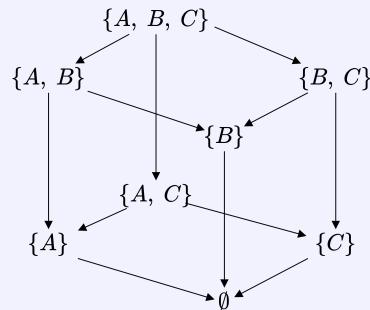

Diagram of  $\subseteq$  for sets  $\subseteq \{A, B, C\}$

Scott solved the most difficult part, considering recursively defined algorithms as continuous functions between domains.

#### 1.4.4 Haskell Programs

Example using a basic implementation of power.

```
-- Precondition: n >= 0
power :: Integer -> Integer -> Integer
power x 0 = 1
power x n = x * power x (n-1)

-- Precondition: n >= 0
power' :: Integer -> Integer -> Integer
power' x 0 = 1
power' x n
| even n = k2
| odd n = x * k2
where
  k = power' x (n `div` 2)
  k2 = k * k
```

**O(n)**

```
power 7 5
~~ 7 * (power 7 4)
~~ 7 * ( 7 * (power 7 3))
~~ 7 * ( 7 * (7 * (power 7 2)))
~~ 7 * ( 7 * (7 * (7 * (power 7 1))))
~~ 7 * ( 7 * (7 * (7 * (7 * (power 7 0)))))
~~ 7 * ( 7 * (7 * (7 * (7 * (7 * 1)))))
~~ 16807
```

**O(log(n)) steps**

```
power' 7 5
~~ 7 * (power' 7 2)̂
~~ 7 * ((power' 7 1)̂)̂
~~ 7 * ((7 * (power' 7 0)̂)̂)̂
~~ 7 * ((7 * (1)̂)̂)̂
~~ 16807
```

These two functions are equivalent in result however operate differently (one much faster than the other).

### 1.5 Program Semantics

#### Denotational Semantics

#### Definition 1.5.1

- A program's meaning is described computationally using denotations (mathematical objects)
- A denotation of a program phrase is built from its sub-phrases.

#### Operational Semantics

#### Definition 1.5.2

Program's meaning is given in terms of the steps taken to make it run.

#### 60007 - The Theory and Practice of Concurrent Programming

#### Extra Fun! 1.5.1

The third-year concurrency module uses both operational and denotational semantics to reason about the correctness of concurrent programs, and possible executions under different memory models (see notes here).

There are also *axiomatic semantics* and *declarative semantics* but we will not cover them here.

# Chapter 2

## While Language

### 2.1 SimpleExp

We can define a simple expression language (*SimpleExp*) to work on:

$$E \in \text{SimpleExp} ::= n \mid E + E \mid E \times E \mid \dots$$

We want semantics that are the same as we would expect in typical mathematics notation

Small-Set/Structural	Definition 2.1.1	Big-Step/Natural	Definition 2.1.2
Gives a method for evaluating an expression step-by-step. $E \rightarrow E'$		Ignores intermediate steps and gives result immediately. $E \Downarrow n$	

We need big to define big and small step semantics for SimpleExp to describe this, and have those semantics conform to several properties listed.

#### 2.1.1 Big-Step Semantics

##### Rules

$$\text{(B-NUM)} \frac{}{n \Downarrow n} \quad \text{(B-ADD)} \frac{E_1 \Downarrow n_1 \quad E_2 \Downarrow n_2}{E_1 + E_2 \Downarrow n_3} \quad n_3 = n_1 + n_2$$

We can similarly define multiplication, subtraction etc.

##### Properties

Determinacy	Definition 2.1.3	Totality	Definition 2.1.4
$\forall E, n_1, n_2. [E \Downarrow n_1 \wedge E \Downarrow n_2 \Rightarrow n_1 = n_2]$ Expression evaluation is deterministic (only one result possible).		$\forall E. \exists n. [E \Downarrow n]$ Every expression evaluates to something.	

Break it!	Example Question 2.1.1
How could we break the totality of SimpleExp?  <hr style="border-top: 1px dashed #ccc;"/> $\text{(B-NON-TOTAL)} \frac{}{true \Downarrow true}$	We can break <i>totality</i> by introducing a rule that can always match its output.  The B-NON-TOTAL rule can be applied indefinitely (possible evaluation path that never finishes).

## Now it all adds up!

## Example Question 2.1.2

Show that  $3 + (2 + 1) \Downarrow 6$  using the provided rules.

We can hence create the derivation:

$$\frac{\text{(B-ADD)} \frac{\text{(B-NUM)} \frac{3 \Downarrow 3}{\text{(B-ADD)}} \text{(B-ADD)} \frac{\text{(B-NUM)} \frac{2 \Downarrow 2}{2 + 1 \Downarrow 3} \text{(B-NUM)} \frac{1 \Downarrow 1}{}}{}}{}}{3 + (2 + 1) \Downarrow 6}$$

### 2.1.2 Small Step Semantics

Given a relation  $\rightarrow$  we can define its transitive closure  $\rightarrow^*$  such that:

$$E \rightarrow^* E' \Leftrightarrow E = E' \vee \exists E_1, E_2, \dots, E_k. [E \rightarrow E_1 \rightarrow E_2 \rightarrow \dots \rightarrow E_k \rightarrow E']$$

#### Rules

$$\begin{aligned} \text{(S-ADD)} & \frac{}{n_1 + n_2 \rightarrow n_3} n_3 = n_1 + n_2 \\ \text{(S-LEFT)} & \frac{E_1 \rightarrow E'_1}{E_1 + E_2 \rightarrow E'_1 + E_2} \quad \text{(S-RIGHT)} \frac{E \rightarrow E'}{n + E \rightarrow n + E'} \end{aligned}$$

Here we define  $+$  as a left-associative operator.

#### Normal Form

#### Definition 2.1.5

$E$  is in its normal form (irreducible) if there is no  $E'$  such that  $E \rightarrow E'$

In *SimpleExp* the normal form is the natural numbers.

#### Properties

##### Confluence

##### Definition 2.1.6

$$\forall E, E_1, E_2. [E \rightarrow^* E_1 \wedge E \rightarrow^* E_2 \Rightarrow \exists E'. [E_1 \rightarrow^* E' \wedge E_2 \rightarrow^* E']]$$

Determinate  $\rightarrow$  Confluent

There are several evaluations paths, but they all get the same end result.

##### Determinacy

##### Definition 2.1.7

$$\forall E, E_1, E_2. [E \rightarrow E_1 \wedge E \rightarrow E_2 \Rightarrow E_1 = E_2]$$

There is at most one next possible step/rule to apply.

##### Strong Normalisation

##### Definition 2.1.8

There are no infinite sequences of expressions, all sequences are finite.

##### Weak Normalisation

##### Definition 2.1.9

$$\forall E. \exists k. \exists n. [E \rightarrow^k n]$$

There is some finite sequence of expressions (to normalize) for any expression.

##### Unique Normal Form

##### Definition 2.1.10

$$\forall E, n_1, n_2. [E \rightarrow^* n_1 \wedge E \rightarrow n_2 \Rightarrow n_1 = n_2]$$

## To be determined...

## Example Question 2.1.3

Add a rule to break determinacy without breaking confluence.

$$\text{(S-RIGHT-E)} \frac{E_2 \rightarrow E'_2}{E_1 + E_2 \rightarrow E_1 + E'_2}$$

As we can now choose which side to reduce first (S-LEFT or S-RIGHT-E), we have lost determinacy, however we retain confluence.

## 2.2 While

### 2.2.1 Syntax

We can define a simple while language (if, else, while loops) to build programs from & to analyse.

$$\begin{aligned} B \in \text{Bool} &::= \text{true} | \text{false} | E = E | E < E | B \& B | \neg B \dots \\ E \in \text{Exp} &::= x | n | E + E | E \times E | \dots \\ C \in \text{Com} &::= x := E | \text{if } B \text{ then } C \text{ else } C | C | \text{skip} | \text{while } B \text{ do } C \end{aligned}$$

Where  $x \in \text{Var}$  ranges over variable identifiers, and  $n \in \mathbb{N}$  ranges over natural numbers.

### 2.2.2 States

#### Partial Function

#### Definition 2.2.1

A mapping of every member of its domain, to at most one member of its codomain.

A *state* is a partial function from variables to numbers (partial function as only defined for some variables). For state  $s$ , and variable  $x$ ,  $s(x)$  is defined, e.g:

$$s = (x \mapsto 2, y \mapsto 200, z \mapsto 20)$$

(In the current state,  $x = 2, y = 200, z = 20$ ).

For example:

$$\begin{aligned} s[x \mapsto 7](u) &= 7 && \text{if } u = x \\ &= s(u) && \text{otherwise} \end{aligned}$$

The *small-step* semantics of *While* are defined using *configurations* of form:

$$\langle E, s \rangle, \langle B, s \rangle, \langle C, s \rangle$$

(Evaluating  $E$ ,  $B$ , or  $C$  with respect to state  $s$ )

We can create a new state, where variable  $x$  equals value  $a$ , from an existing state  $s$ :

$$s'(u) \triangleq \alpha(x) = \begin{cases} a & u = x \\ s(u) & \text{otherwise} \end{cases}$$

$$s' = s[x \mapsto u] \text{ is equivalent to } \text{dom}(s') = \text{dom}(s) \wedge \forall y. [y \neq x \rightarrow s(y) = s'(y) \wedge s'(x) = a]$$

( $s'$  equals  $s$  where  $x$  maps to  $a$ )

### 2.2.3 Rules

#### Expressions

$$\begin{array}{ll} (\text{W-EXP.LEFT}) \frac{\langle E_1, s \rangle \rightarrow_e \langle E'_1, s' \rangle}{\langle E_1 + E_2, s \rangle \rightarrow_e \langle E'_1 + E_2, s' \rangle} & (\text{W-EXP.RIGHT}) \frac{\langle E, s \rangle \rightarrow_e \langle E', s' \rangle}{\langle n + E, s \rangle \rightarrow_e \langle n + E', s' \rangle} \\ (\text{W-EXP.VAR}) \frac{}{\langle x, s \rangle \rightarrow_e \langle n, s \rangle} s(x) = n & (\text{W-EXP.ADD}) \frac{}{\langle n_1 + n_2, s \rangle} \langle n_3, s \rangle n_3 = n_1 + n_2 \end{array}$$

These rules allow for side effects, despite the While language being side effect free in expression evaluation. We show this by changing state  $s \rightarrow_e s'$ .

We can show inductively (from the base cases W-EXP.VAR and W-EXP.ADD) that expression evaluation is side effect free.

#### Booleans

(Based on expressions, one can create the same for booleans) ( $b \in \{\text{true}, \text{false}\}$ )

$$\begin{array}{ll} (\text{W-BOOL.AND.LEFT}) \frac{\langle B_1, s \rangle \rightarrow_b \langle B'_1, s' \rangle}{\langle B_1 \& B_2, s \rangle \rightarrow_b \langle B'_1 \& B_2, s' \rangle} & (\text{W-BOOL.AND.RIGHT}) \frac{\langle B, s \rangle \rightarrow_b \langle B', s' \rangle}{\langle b \& B_2, s \rangle \rightarrow_b \langle b \& B', s' \rangle} \\ (\text{W-BOOL.AND.TRUE}) \frac{}{\langle \text{true} \& \text{true}, s \rangle \rightarrow_b \langle \text{true}, s \rangle} & (\text{W-BOOL.AND.FALSE}) \frac{}{\langle \text{false} \& b, s \rangle \rightarrow_b \langle \text{true}, s \rangle} \end{array}$$

(Notice we do not short circuit, as the right arm may change the state. In a side effect free language, we could.)

$$\begin{array}{ll}
 (\text{W-BOOL.EQUAL.LEFT}) \frac{\langle E_1, s \rangle \rightarrow_e \langle E'_1, s' \rangle}{\langle E_1 = E_2, s \rangle \rightarrow_b \langle E'_1 = E_2, s' \rangle} & (\text{W-BOOL.EQUAL.RIGHT}) \frac{\langle E, s \rangle \rightarrow_e \langle E', s' \rangle}{\langle n = E, s \rangle \rightarrow_b \langle n = E, s' \rangle} \\
 (\text{W-BOOL.EQUAL.TRUE}) \frac{}{\langle n_1 = n_2, s \rangle \rightarrow_b \langle \text{true}, s \rangle} n_1 = n_2 & (\text{W-BOOL.EQUAL.FALSE}) \frac{}{\langle n_1 = n_2, s \rangle \rightarrow_b \langle \text{false}, s \rangle} n_1 \neq n_2 \\
 (\text{W-BOOL.LESS.LEFT}) \frac{\langle E_1, s \rangle \rightarrow_e \langle E'_1, s' \rangle}{\langle E_1 < E_2, s \rangle \rightarrow_b \langle E'_1 < E_2, s' \rangle} & (\text{W-BOOL.LESS.RIGHT}) \frac{\langle E, s \rangle \rightarrow_e \langle E', s' \rangle}{\langle n < E, s \rangle \rightarrow_b \langle n < E, s' \rangle} \\
 (\text{W-BOOL.LESS.TRUE}) \frac{}{\langle n_1 < n_2, s \rangle \rightarrow_b \langle \text{true}, s \rangle} n_1 < n_2 & (\text{W-BOOL.EQUAL.FALSE}) \frac{}{\langle n_1 < n_2, s \rangle \rightarrow_b \langle \text{false}, s \rangle} n_1 \geq n_2 \\
 (\text{W-BOOL.NOT}) \frac{}{\langle \neg \text{true}, s \rangle \rightarrow_b \langle \text{false}, s \rangle} & (\text{W-BOOL.NOT}) \frac{}{\langle \neg \text{false}, s \rangle \rightarrow_b \langle \text{true}, s \rangle}
 \end{array}$$

### Assignment

$$(\text{W-ASS.EXP}) \frac{\langle E, s \rangle \rightarrow_e \langle E', s' \rangle}{\langle x := E, s \rangle \rightarrow_c \langle x := E', s' \rangle} \quad (\text{W-ASS.NUM}) \frac{}{\langle x := n, s \rangle \rightarrow_c \langle \text{skip}, s[x \mapsto n] \rangle}$$

### Sequential Composition

$$(\text{W-SEQ.LEFT}) \frac{\langle C_1, s \rangle \rightarrow_c \langle C'_1, s' \rangle}{\langle C_1; C_2, s \rangle \rightarrow_c \langle C'_1; C_2, s' \rangle} \quad (\text{W-SEQ.SKIP}) \frac{}{\langle \text{skip}; C, s \rangle \rightarrow_c \langle C, s \rangle}$$

### Conditionals

$$\begin{array}{l}
 (\text{W-COND.TRUE}) \frac{}{\langle \text{if } \text{true} \text{ then } C_1 \text{ else } C_2, s \rangle \rightarrow_c \langle C_1, s \rangle} \\
 (\text{W-COND.FALSE}) \frac{}{\langle \text{if } \text{false} \text{ then } C_1 \text{ else } C_2, s \rangle \rightarrow_c \langle C_2, s \rangle} \\
 (\text{W-COND.BEXP}) \frac{\langle B, s \rangle \rightarrow_b \langle B', s' \rangle}{\langle \text{if } B \text{ then } C_1 \text{ else } C_2, s \rangle \rightarrow_c \langle \text{if } B' \text{ then } C_1 \text{ else } C_2, s' \rangle}
 \end{array}$$

### While

$$(\text{W-WHILE}) \frac{}{\langle \text{while } B \text{ do } C, s \rangle \rightarrow_c \langle \text{if } B \text{ then } (C; \text{while } B \text{ do } C) \text{ else skip}, s \rangle}$$

### 2.2.4 Properties

The execution relation ( $\rightarrow_c$ ) is deterministic.

$$\forall C, C_1, C_2 \in \text{Com} \forall s, s_1, s_2. [\langle C, s \rangle \rightarrow_c \langle C_1, s_1 \rangle \wedge \langle C, s \rangle \rightarrow_c \langle C_2, s_2 \rangle \rightarrow \langle C_1, s_1 \rangle = \langle C_2, s_2 \rangle]$$

Hence the relation is also confluent:

$$\begin{aligned}
 \forall C, C_1, C_2 \in \text{Com} \forall s, s_1, s_2. [\langle C, s \rangle \rightarrow_c \langle C_1, s_1 \rangle \wedge \langle C, s \rangle \rightarrow_c \langle C_2, s_2 \rangle \rightarrow \\
 \exists C' \in \text{Com}, s'. [\langle C_1, s_1 \rangle \rightarrow_c \langle C', s' \rangle \wedge \langle C_2, s_2 \rangle \rightarrow_c \langle C', s' \rangle]]
 \end{aligned}$$

Both also hold for  $\rightarrow_e$  and  $\rightarrow_b$ .

### 2.2.5 Configurations

#### Answer Configuration

A configuration  $\langle \text{skip}, s \rangle$  is an *answer configuration*. As there is no rule to execute skip, it is a normal form.

$$\neg \exists C \in \text{Com}, s, s'. [\langle \text{skip}, s \rangle \rightarrow_c \langle C, s' \rangle]$$

For booleans  $\langle \text{true}, s \rangle$  and  $\langle \text{false}, s \rangle$  are answer configurations, and for expressions  $\langle n, s \rangle$ .

#### Stuck Configurations

A configuration that cannot be evaluated to a normal form is called a *stuck configuration*.

$$\langle y, (x \mapsto 3) \rangle$$

Note that a configuration that leads to a *stuck configuration* is not itself stuck.

$$\langle 5 < y, (x \mapsto 2) \rangle$$

(Not stuck, but reduces to a stuck state)

## 2.2.6 Normalising

The relations  $\rightarrow_b$  and  $\rightarrow_e$  are normalising, but  $\rightarrow_c$  is not as it may not have a normal form.

while *true* do *skip*

$$\langle \text{while } \textit{true} \text{ do } \textit{skip}, s \rangle \xrightarrow{3} \langle \text{while } \textit{true} \text{ do } \textit{skip}, s \rangle$$

( $\rightarrow_c^3$  means 3 steps, as we have gone through more than one to get the same configuration, it is an infinite loop)

## 2.2.7 Side Effecting Expressions

If we allow programs such as:

$$\text{do } x := x + 1 \text{ return } x$$

$$(\text{do } x := x + 1 \text{ return } x) + (\text{do } x := x \times 1 \text{ return } x)$$

(value depends on evaluation order)

## 2.2.8 Short Circuit Semantics

$$\frac{B_1 \rightarrow_b B'_1}{B_1 \& B_2 \rightarrow_b B'_1 \& B_2} \quad \frac{}{\text{false} \& B \rightarrow_b \text{false}} \quad \frac{}{\text{true} \& B \rightarrow_b B}$$

## 2.2.9 Strictness

An operation is *strict* when arguments must be evaluated before the operation is evaluated. Addition is strict as both expressions must be evaluated (left, then right).

Due to short circuiting,  $\&$  is left strict as it is possible for the operation to be evaluated without evaluating the right (*non-strict* in right argument).

## 2.2.10 Complex Programs

It is now possible to build complex programs to be evaluated with our small step rules.

$$\text{Factorial} \triangleq y := x; a := 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1)$$

We can evaluate *Factorial* with an input  $s = [x \mapsto \dots]$  to get answer configuration  $[\dots, a \mapsto x!, x \mapsto \dots]$

Execute!	Example Question 2.2.1
<p>Evaluate <i>Factorial</i> for the following initial configuration:  <math>s = [x \mapsto 3, y \mapsto 17, z \mapsto 42]</math></p>	<p><b>Start</b>  <math>\langle y := x; a := 1; \text{while } 0 &lt; y \text{ do } (a := a \times y; y := y - 1), [x \mapsto 3, y \mapsto 17, z \mapsto 42] \rangle</math></p> <p><b>Get x variable</b>  where <math>C = a := 1; \text{while } 0 &lt; y \text{ do } (a := a \times y; y := y - 1)</math> and <math>s = (x \mapsto 3, y \mapsto 17, z \mapsto 42)</math>:</p> $ \begin{array}{c} (\text{W-EXP.VAR}) \frac{}{\langle x, s \rangle \rightarrow_e \langle 3, s \rangle} \\ (\text{W-ASS.EXP}) \frac{}{\langle y := x, s \rangle \rightarrow_c \langle y := 3, s \rangle} \\ (\text{W-SEQ.LEFT}) \frac{}{\langle y := x; C, s \rangle \rightarrow_c \langle y := 3; C, s \rangle} \end{array} $ <p><b>Result:</b>  <math>\langle y := 3; a := 1; \text{while } 0 &lt; y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 17, z \mapsto 42) \rangle</math></p> <p><b>Assign to y variable</b>  where <math>C = a := 1; \text{while } 0 &lt; y \text{ do } (a := a \times y; y := y - 1)</math> and <math>s = (x \mapsto 3, y \mapsto 17, z \mapsto 42)</math>:</p> $ \begin{array}{c} (\text{W-ASS.NUM}) \frac{}{\langle y := 3, s \rangle \rightarrow_c \langle \text{skip}, s[y \mapsto 3] \rangle} \\ (\text{W-SEQ.LEFT}) \frac{}{\langle y := 3; C, s \rangle \rightarrow_c \langle \text{skip}; C, s[y \mapsto 3] \rangle} \end{array} $ <p><b>Result:</b>  <math>\langle \text{skip}; a := 1; \text{while } 0 &lt; y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 3, z \mapsto 42) \rangle</math></p>

### Eliminate skip

where  $C = a := 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1)$  and  $s = (x \mapsto 3, y \mapsto 3, z \mapsto 42)$ :

$$(\text{W-SEQ.SKIP}) \frac{}{\langle \text{skip}; C, s \rangle \rightarrow_c \langle C, s \rangle}$$

Result:

$$\langle a := 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 3, z \mapsto 42) \rangle$$

### Assign a

where  $C = \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1)$  and  $s = (x \mapsto 3, y \mapsto 3, z \mapsto 42)$ :

$$(\text{W-SEQ.LEFT}) \frac{(\text{W-ASS.NUM}) \frac{}{\langle a := 1, s \rangle \rightarrow_c \langle \text{skip}, s[a \mapsto 1] \rangle}}{\langle a := 1; C, s \rangle \rightarrow_c \langle \text{skip}; C, s[a \mapsto 1] \rangle}$$

Result:

$$\langle \text{skip}; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1) \rangle$$

### Eliminate skip

where  $C = \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1)$  and  $s = (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1)$ :

$$(\text{W-SEQ.SKIP}) \frac{}{\langle \text{skip}; C, s \rangle \rightarrow_c \langle C, s \rangle}$$

Result:

$$\langle \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1) \rangle$$

### Expand while

where  $C = (a := a \times y; y := y - 1)$ ,  $B = 0 < y$  and  $s = (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1)$ :

$$(\text{W-WHILE}) \frac{}{\langle \text{while } B \text{ do } C, s \rangle \rightarrow_c \langle \text{if } B \text{ then } (C; \text{while } B \text{ do } C) \text{ else skip}, s \rangle}$$

Result:

$$\langle \text{if } 0 < y \text{ then } (a := a \times y; y := y - 1); \text{while } 0 < y \text{ do } a := a \times y; y := y - 1) \text{ else skip}, (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1) \rangle$$

### Get y variable

where  $C = (a := a \times y; y := y - 1)$  and  $s = (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1)$ :

$$(\text{W-COND.BEXP}) \frac{(\text{W-EXP.VAR}) \frac{}{\langle y, s \rangle \rightarrow \langle 3, s \rangle}}{(\text{W-BOOL.LESS.RIGHT}) \frac{}{\langle 0 < y, s \rangle \rightarrow_b \langle 0 < 3, s \rangle}} \frac{}{\langle \text{if } 0 < y \text{ then } (C; \text{while } 0 < y \text{ do } C) \text{ else skip}, s \rangle \rightarrow_c \langle \text{if } 0 < 3 \text{ then } (C; \text{while } 0 < y \text{ do } C) \text{ else skip}, s \rangle}$$

Result:

$$\langle \text{if } 0 < 3 \text{ then } (a := a \times y; y := y - 1); \text{while } 0 < y \text{ do } a := a \times y; y := y - 1) \text{ else skip}, (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1) \rangle$$

### Complete if boolean

where  $C = (a := a \times y; y := y - 1)$  and  $s = (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1)$ :

$$(\text{W-COND.EXP}) \frac{(\text{W-BOOL.LESS.TRUE}) \frac{}{\langle 0 < 3, s \rangle \rightarrow_b \langle \text{true}, s \rangle}}{\langle \text{if } 0 < 3 \text{ then } (C; \text{while } 0 < y \text{ do } C) \text{ else skip}, s \rangle \rightarrow_c \langle \text{if true then } (C; \text{while } 0 < y \text{ do } C) \text{ else skip}, s \rangle}$$

Result:

$$\langle \text{if true then } (a := a \times y; y := y - 1); \text{while } 0 < y \text{ do } a := a \times y; y := y - 1) \text{ else skip}, (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1) \rangle$$

### Evaluate if

where  $C = (a := a \times y; y := y - 1)$  and  $s = (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1)$ :

$$(\text{W-COND.TRUE}) \frac{}{\langle \text{if true then } (C; \text{while } 0 < y \text{ do } C) \text{ else skip}, s \rangle \rightarrow_c \langle C; \text{while } 0 < y \text{ do } C, s \rangle}$$

Result:

$$\langle a := a \times y; y := y - 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1) \rangle$$

### Evaluate Expression a

where  $C = y := y - 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1) \text{ and } s = (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1)$ :

$$\frac{\begin{array}{c} (\text{W-EXP.VAR}) \frac{\langle a, s \rangle \rightarrow \langle 1, s \rangle}{\langle a \times y, s \rangle \rightarrow_e \langle 1 \times y, s \rangle} \\ (\text{W-EXP.MUL.LEFT}) \frac{}{\langle a := a \times y, s \rangle \rightarrow_c \langle a := 1 \times y, s \rangle} \\ (\text{W-ASS.EXP}) \end{array}}{(\text{W-SEQ.LEFT}) \frac{}{\langle a := a \times y; C, s \rangle \rightarrow_c \langle a := 1 \times y; C, s \rangle}}$$

Result:

$$\langle a := 1 \times y; y := y - 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1) \rangle$$

### Evaluate Expression y

where  $C = y := y - 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1) \text{ and } s = (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1)$ :

$$\frac{\begin{array}{c} (\text{W-EXP.VAR}) \frac{\langle y, s \rangle \rightarrow_e \langle 3, s \rangle}{\langle 1 \times y, s \rangle \rightarrow_e \langle 1 \times 3, s \rangle} \\ (\text{W-EXP.MUL.RIGHT}) \frac{}{\langle a := 1 \times y, s \rangle \rightarrow_c \langle a := 1 \times 3, s \rangle} \\ (\text{W-ASS.EXP}) \end{array}}{(\text{W-SEQ.LEFT}) \frac{}{\langle a := 1 \times y; C, s \rangle \rightarrow \langle a := 1 \times 3; C, s \rangle}}$$

Result:

$$\langle a := 1 \times 3; y := y - 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1) \rangle$$

### Evaluate Multiply

where  $C = y := y - 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1) \text{ and } s = (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1)$ :

$$\frac{\begin{array}{c} (\text{W-EXP.MUL}) \frac{\langle 1 \times 3, s \rangle \rightarrow_e \langle 3, s \rangle}{\langle a := 1 \times 3, s \rangle \rightarrow_c \langle a := 3, s \rangle} \\ (\text{W-ASS.EXP}) \end{array}}{(\text{W-SEQ.LEFT}) \frac{}{\langle a := 1 \times 3; C, s \rangle \rightarrow_c \langle a := 3; C, s \rangle}}$$

Result:

$$\langle a := 3; y := y - 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1) \rangle$$

### Assign 3 to a

where  $C = y := y - 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1) \text{ and } s = (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 1)$ :

$$\frac{(\text{W-ASS.NUM}) \frac{\langle a := 3, s \rangle \rightarrow_c \langle \text{skip}, s[a \mapsto 3] \rangle}{\langle a := 3; C, s \rangle \rightarrow_c \langle \text{skip}; C, s[a \mapsto 3] \rangle}}{(\text{W-SEQ.LEFT}) \frac{}{\langle a := 3; C, s \rangle \rightarrow_c \langle \text{skip}; C, s[a \mapsto 3] \rangle}}$$

Result:

$$\langle \text{skip}; y := y - 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 3) \rangle$$

### Eliminate Skip

where  $C = y := y - 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1) \text{ and } s = (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 3)$ :

$$\frac{(\text{W-SEQ.SKIP}) \frac{\langle \text{skip}; C, s \rangle \rightarrow_c \langle C, s \rangle}{\langle y := y - 1; C, s \rangle \rightarrow_c \langle C, s \rangle}}{(\text{W-SEQ.SKIP}) \frac{}{\langle \text{skip}; C, s \rangle \rightarrow_c \langle C, s \rangle}}$$

Result:

$$\langle y := y - 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 3) \rangle$$

### Assign 3 to y

where  $C = \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1) \text{ and } s = (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 3)$ :

$$\frac{\begin{array}{c} (\text{W-EXP.VAR}) \frac{\langle y, s \rangle \rightarrow \langle 3, s \rangle}{\langle y - 1, s \rangle \rightarrow_e \langle 3 - 1, s \rangle} \\ (\text{W-EXP.SUB.LEFT}) \frac{}{\langle y := y - 1, s \rangle \rightarrow_c \langle y := 3 - 1, s \rangle} \\ (\text{W-ASS.EXP}) \end{array}}{(\text{W-SEQ.LEFT}) \frac{}{\langle y := y - 1; C, s \rangle \rightarrow_c \langle y := 3 - 1, s \rangle}}$$

Result:

$$\langle y := 3 - 1; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 3) \rangle$$

### Evaluate Subtraction

where  $C = \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1)$  and  $s = (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 3)$ :

$$\frac{\begin{array}{c} (\text{W-EXP.SUB}) \frac{}{\langle 3 - 1, s \rangle \rightarrow_e \langle 2, s \rangle} \\ (\text{W-ASS.EXP}) \frac{}{\langle y := 3 - 1, s \rangle \rightarrow_c \langle y := 2, s \rangle} \end{array}}{(\text{W-SEQ.LEFT}) \frac{}{\langle y := 3 - 1; C, s \rangle \rightarrow_c \langle y := 2; C, s \rangle}}$$

Result:

$$\langle y := 2; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 3) \rangle$$

### Assign 2 to y

where  $C = \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1)$  and  $s = (x \mapsto 3, y \mapsto 3, z \mapsto 42, a \mapsto 3)$ :

$$\frac{\begin{array}{c} (\text{W-ASS.NUM}) \frac{}{\langle y := 2, s \rangle \rightarrow_c \langle \text{skip}, s[y \mapsto 2] \rangle} \\ (\text{W-SEQ.LEFT}) \frac{}{\langle y := 2; C, s \rangle \rightarrow_c \langle \text{skip}; C, s[y \mapsto 2] \rangle} \end{array}}{(\text{W-SEQ.LEFT}) \frac{}{\langle y := 2; C, s \rangle \rightarrow_c \langle \text{skip}; C, s[y \mapsto 2] \rangle}}$$

Result:

$$\langle \text{skip}; \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 2, z \mapsto 42, a \mapsto 3) \rangle$$

### Eliminate skip

where  $C = \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1)$  and  $s = (x \mapsto 3, y \mapsto 2, z \mapsto 42, a \mapsto 3)$ :

$$\frac{(\text{W-SEQ.SKIP}) \frac{}{\langle \text{skip}; C, s \rangle \rightarrow_c \langle C, s \rangle}}{(\text{W-SEQ.LEFT}) \frac{}{\langle \text{skip}; C, s \rangle \rightarrow_c \langle C, s \rangle}}$$

Result:

$$\langle \text{while } 0 < y \text{ do } (a := a \times y; y := y - 1), (x \mapsto 3, y \mapsto 2, z \mapsto 42, a \mapsto 3) \rangle$$

**UNFINISHED!!!**

# Chapter 3

## Structural Induction

### 3.1 Motivation

Structural induction is used for reasoning about collections of objects, which are:

- structured in a well defined way
- finite but can be arbitrarily large and complex

We can use this reason about:

- natural numbers
- data structures (lists, trees, etc)
- programs (can be large, but are finite)
- derivations of assertions like  $E \Downarrow 4$  (finite trees of axioms and rules)

### Structural Induction over Natural Numbers

$$\mathbb{N} \in Nat ::= zero | succ(\mathbb{N})$$

To prove a property  $P(\mathbb{N})$  holds, for every number  $N \in Nat$  by induction on structure  $\mathbb{N}$ :

**Base Case** Prove  $P(zero)$

**Inductive Case** Prove  $P(succ(K))$  when  $P(K)$  holds

For example, we can prove the property:

$$plus(\mathbb{N}, zero) = \mathbb{N}$$

#### Base Case

Show  $plus(zero, zero) = zero$

$$\begin{aligned} (1) \quad LHS &= plus(zero, zero) \\ (2) &= zero && \text{(By definition of } plus\text{)} \\ (3) &= RHS && \text{(As Required)} \end{aligned}$$

#### Inductive Case

$$N = succ(K)$$

Inductive Hypothesis  $plus(K, zero) = K$

Show  $plus(succ(K), zero) = succ(K)$

$$\begin{aligned} (1) \quad LHS &= plus(succ(K), zero) \\ (2) &= succ(plus(K, zero)) && \text{(By definition of } plus\text{)} \\ (3) &= succ(K) && \text{(By Inductive Hypothesis)} \\ (4) &= RHS && \text{(As Required)} \end{aligned}$$

Mathematics induction is a special case of structural induction:

$$P(0) \wedge [\forall k \in \mathbb{N}. P(k) \Rightarrow P(k + 1)]$$

In the exam you may use  $P(0)$  and  $P(K + 1)$  rather than  $P(zero)$  and  $P(succ(k))$  to save time.

### 3.1.1 Binary Trees

$$bTree \in BinaryTree ::= Node \mid Branch(bTree, bTree)$$

We can define a function *leaves*:

$$\begin{aligned} leaves(Node) &= 1 \\ leaves(Branch(T_1, T_2)) &= leaves(T_1) + leaves(T_2) \end{aligned}$$

Or *branches*:

$$\begin{aligned} branches(Node) &= 0 \\ branches(Branch(T_1, T_2)) &= branches(T_1) + branches(T_2) + 1 \end{aligned}$$

P

Example Question 3.1.1

Prove By induction that  $leaves(T) = branches(T) + 1$

**UNFINISHED!!!**

## 3.2 Induction over SimpleExp

To define a function on all expressions in *SimpleExp*:

- define  $f(n)$  directly, for each number  $n$ .
- define  $f(E_1 + E_2)$  in terms of  $f(E_1)$  and  $f(E_2)$ .
- define  $f(E_1 \times E_2)$  in terms of  $f(E_1)$  and  $f(E_2)$ .

For example, we can do this with *den*:

$$den(E) = n \leftrightarrow E \Downarrow n$$

### 3.2.1 Many Steps of Evaluation

Given  $\rightarrow$  we can define a new relation  $\rightarrow^*$  as:

$$E \rightarrow^* E' \leftrightarrow (E = E' \vee E \rightarrow E_1 \rightarrow E_2 \rightarrow \dots \rightarrow E_k \rightarrow E')$$

For expressions, the final answer is  $n$  if  $E \rightarrow^* n$ .

### 3.2.2 Multi-Step Reductions

The relation  $E \rightarrow^n E'$  is defined using mathematics induction by:

**Base Case**

$$\forall E \in SImpleExp. [E \rightarrow^0 E]$$

**Inductive Case**

$$\forall E, E' \in SimpleExp. [E \rightarrow^{k+1} E' \Leftrightarrow \exists E''. [E \rightarrow^k E'' \wedge E'' \rightarrow E']]$$

**Definition**

$$\forall E, E'. [E \rightarrow^* E' \Leftrightarrow \exists n. [E \rightarrow^n E']]$$

$\rightarrow^*$  - there are some number of steps to evaluate to  $E'$

### Properties of $\rightarrow$

Determinacy	If $E \rightarrow E_1$ and $E \rightarrow E_2$ then $E_1 = E_2$ .
Confluence	If $E \rightarrow^* E_1$ and $E \rightarrow^* E_2$ then there exists $E'$ such that $E_1 \rightarrow^* E'$ and $E_2 \rightarrow^* E'$ .
Unique answer	If $E \rightarrow^* n_1$ and $E \rightarrow^* n_2$ then $n_1 = n_2$ .
Normal Forms	Normal form is numbers ( $\mathbb{N}$ ) for any $E$ , $E = n$ or $E \rightarrow E'$ for some $E'$ .
Normalisation	No infinite sequences of expressions $E_1, E_2, E_3, \dots$ such that for all $i \in \mathbb{N}$ $E_i \rightarrow E_{i+1}$ (Every path goes to a normal form).

### 3.2.3 Confluence of Small Step

We can prove a lemma expressing confluence:

$$L_1 : \forall n \in \mathbb{N}. \forall E, E_1, E_2 \in SimpleExp. [E \rightarrow^n E_1 \wedge E \rightarrow^* E_2 \Rightarrow \exists E' \in SimpleExp. [E_1 \rightarrow^* E' \wedge E_2 \rightarrow^* E']]$$

#### Lemma $\Rightarrow$ Confluence

Confluence is:  $\forall E, E_1, E_2 \in SimpleExp. [E \rightarrow^* E_1 \wedge E \rightarrow^* E_2 \Rightarrow \exists E' \in SimpleExp. [E_1 \rightarrow^* E' \wedge E_2 \rightarrow^* E']]$  From lemma  $L_1$

- (1) Take some arbitrary  $E, E_1, E_2 \in SimpleExp$ , assume confluence holds. (Initial Setup)
- (2)  $E \rightarrow^* E_1$  (By Confluence)
- (3)  $\exists n \in \mathbb{N}. [E \rightarrow^n E_1]$  (By 2 & definition of  $\rightarrow^*$ )
- (4) Hence  $L_1$  (By 3)

### 3.2.4 Determinacy of Small Step

We create a property  $P$ :

$$P(E) \stackrel{\text{def}}{=} \forall E_1, E_2 \in SimpleExp. [E \rightarrow E_1 \wedge E \rightarrow E_2 \Rightarrow E_1 = E_2]$$

There are 3 rules that apply:

$$(A) \frac{}{n_1 + n_2 \rightarrow n} \quad n = n_1 + n_2 \quad (B) \frac{E \rightarrow E'}{n + E \rightarrow n + E'} \quad (C) \frac{E_1 \rightarrow E'_1}{E_1 + E_2 \rightarrow E'_1 + E_2}$$

#### Base Case

Take arbitrary  $n \in \mathbb{N}$  and  $E_1, E_2 \in SimpleExp$  such that  $n \rightarrow E_1 \wedge n \rightarrow E_2$  to show  $E_1 = E_2$ .

- (1)  $n \not\rightarrow$  (By inversion on A,B & C)
- (2)  $\neg(n \rightarrow E_1)$  (By 1)
- (3)  $\neg(n \rightarrow E_1 \wedge n \rightarrow E_2)$  (By 2)
- (4)  $n \rightarrow E_1 \wedge n \rightarrow E_2 \Rightarrow E_1 = E_2$  (By 3)
- (5)  $E \rightarrow E_1 \wedge E \rightarrow E_2 \Rightarrow E_1 = E_2$  (By 4)

Hence  $P(n)$

#### Inductive Step

Take arbitrary  $E, E_1, E_2$  such that  $E = E_1 + E_2$

Inductive Hypothesis:

$$IH_1 = P(E_1)$$

$$IH_2 = P(E_2)$$

Assume there exists  $E_3, E_4 \in SimpleExp$  such that  $E_1 + E_2 \rightarrow E_3$  and  $E_1 + E_2 \rightarrow E_4$ .

To show  $E_3 = E_4$ .

From inversion on A, B & C there are 3 cases to consider:

#### For A:

- (1) There exists  $n_1, n_2 \in \mathbb{N}$  such that  $E_1 = n_1$  and  $E_2 = n_2$  (By case A)
- (3)  $E_3 = n_1 + n_2$  (By 1, A)
- (4)  $E_4 = n_1 + n_2$  (By 1, A)
- (5)  $E_3 = E_4$  (By 3 & 4)

#### For B:

- (1) There exists  $n \in \mathbb{N}$  such that  $E_1 = n$  (By case B)
- (2) There exists  $E' \in SimpleExp$  such that  $E_2 \rightarrow E'$  (By case B)
- (3)  $E_3 = n + E'$  (By case B)
- (4) There exists  $E'' \in SimpleExp$  such that  $E_2 \rightarrow E''$  (By case B)
- (5)  $E_4 = n + E''$  (By case B)
- (6)  $E' = E''$  (By  $IH_2$ )
- (7)  $E_3 = E_4$  (By 3,5 & 6)

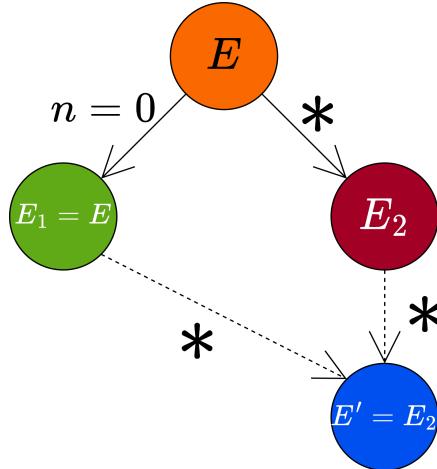

#### For C:

- (1) There exists  $E' \in SimpleExp$  such that  $E_1 \rightarrow E'$  (By case C)
- (2) There exists  $E'' \in SimpleExp$  such that  $E_1 \rightarrow E''$  (By case C)
- (3)  $E_3 = E' + E_2$  (By case C)
- (4)  $E_4 = E'' + E_2$  (By case C)
- (5)  $E' = E''$  (By  $IH_1$ )
- (6)  $E_3 = E_4$  (By 3,4 & 5)

(If  $E$  reduces to  $E_1$  in  $n$  steps, and to  $E_2$  in some number of steps, then there must be some  $E'$  that  $E_1$  and  $E_2$  reduce to.)

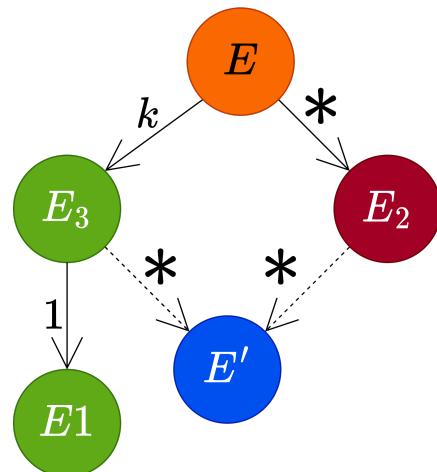

### Base Case

The base cases has  $n = 0$ . Hence  $E = E_1$ , and hence  $E_1 \rightarrow^* E_2$  and  $E_1 \rightarrow^* E'$

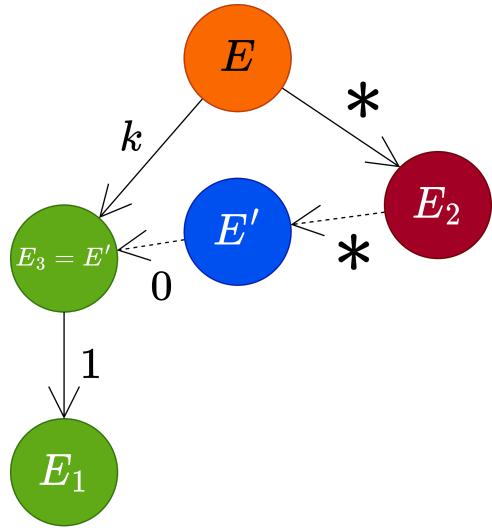

### Inductive Case

Next we assume confluence for up to  $k$  steps, and attempt to prove for  $k + 1$  steps.

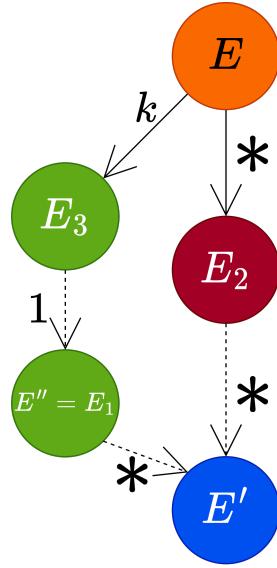

We have two cases:

**Case 1:**  $E_3 = E'$ , this is easy as  $E_2 \rightarrow^* E' \rightarrow^0 E3 \rightarrow^1 E1$ .

**Case 2:**  $E_3 \rightarrow^1 E'' \rightarrow^* E'$ , in this case as  $E_3 \rightarrow^1 E_1$  we know by determinacy that  $E'' = E_1$  and hence  $E_1 \rightarrow^* E'$ .

### 3.3 Multi-Step Reductions

Note: We will reference to state by set  $\text{State} \triangleq (\text{Var} \rightarrow \mathbb{N})$ .

Lemma	Definition 3.3.1
A small proven proposition that can be used in a proof. Used to make the proof smaller.  Also known as an "auxiliary theorem" or "helper theorem".	
Corollary	Definition 3.3.2
A theorem connected by a short proof to another existing theorem.  If B is easily deduced from A (or is evident in A's proof) then B is a corollary of A.	

#### 3.3.1 Lemmas

1.  $\forall r \in \mathbb{N}. \forall E_1, E'_1, E_2 \in \text{SimpleExp}. [E_1 \rightarrow^r E'_1 \Rightarrow (E_1 + E_2) \rightarrow^r (E'_1 + E_2)]$
2.  $\forall r, n \in \mathbb{N}. \forall E_2, E'_2 \in \text{SimpleExp}. [E_2 \rightarrow^r E'_2 \Rightarrow (n + E_2) \rightarrow^r (n + E'_2)]$

### 3.3.2 Corollaries

1.  $\forall n_1 \in \mathbb{N}. \forall E_1, E_2 \in SimpleExp. [E_1 \rightarrow^* n_1 \Rightarrow (E_1 + E_2) \rightarrow^* (n_1 + E_2)]$
2.  $\forall n_1, n_2 \in \mathbb{N}. \forall E_2 \in SimpleExp. [E_2 \rightarrow^* n_2 \Rightarrow (n_1 + E_2) \rightarrow^* (n_1 + n_2)]$
3.  $\forall n, n_1, n_2 \in \mathbb{N}. \forall E_1, E_2 \in SimpleExp. [E_1 \rightarrow^* n_1 \wedge E_2 \rightarrow^* n_2 \wedge n = n_1 + n_2 \Rightarrow (E_1 + E_2) \rightarrow^* n]$

### 3.3.3 Connecting $\Downarrow$ and $\rightarrow^*$ for SimpleExp

$$\forall E \in SimpleExp, n \in \mathbb{N}. [E \Downarrow n \Leftrightarrow E \rightarrow^* n]$$

We prove each direction of implication separately. First we prove by induction over  $E$  using the property  $P$ :

$$P(E) =_{\text{def}} \forall n \in \mathbb{N}. [E \Downarrow n \Rightarrow E \rightarrow^* n]$$

#### Base Case

Take arbitrary  $m \in \mathbb{N}$  to show  $P(m) = m \Downarrow n \Rightarrow m \rightarrow^* n$ .

- (1) Assume  $m \Downarrow n$
- (2)  $m = n$  (From Inversion of  $\Downarrow$ )
- (3)  $m \rightarrow^* n$  (By 2 and definition of  $\rightarrow^*$ )

#### Inductive Step

Take some arbitrary  $E, E_1, E_2$  such that  $E = E_1 + E_2$ .

Inductive Hypothesis

$$\forall n_1 \in \mathbb{N}. [E_1 \Downarrow n_1 \Rightarrow E_1 \rightarrow^* n_1]$$

$$\forall n_2 \in \mathbb{N}. [E_2 \Downarrow n_2 \Rightarrow E_2 \rightarrow^* n_2]$$

To show  $P(E)$ :  $\forall n \in \mathbb{N}. [(E_1 + E_2) \Downarrow n \Rightarrow (E_1 + E_2) \rightarrow^* n]$ .

- (1) Assume  $(E_1 + E_2) \Downarrow n$
- (2)  $\exists n_1, n_2 \in \mathbb{N}. [E_1 \Downarrow n_1 \wedge E_2 \Downarrow n_2]$  (By 1 & definition of B-ADD)
- (3)  $E_1 \rightarrow^* n_1$  (By 2 & IH)
- (4)  $E_2 \rightarrow^* n_2$  (By 2 & IH)
- (5) Choose some  $n \in \mathbb{N}$  such that  $n = n_1 + n_2$
- (6)  $(E_1 + E_2) \rightarrow^* n$  (By 3,4,5 Corollary 3)
- (7)  $E \rightarrow^* n$  (By 6, definition of  $E$ )

Hence assuming  $E \Downarrow n$  implies  $E \rightarrow^* n$ , so  $P(E)$ .

Next we work the other way, to show:

$$\forall E \in SimpleExp. \forall n \in \mathbb{N}. [E \rightarrow^* n \Rightarrow E \Downarrow n]$$

- (1) Take arbitrary  $E \in SimpleExp$  such that  $E \rightarrow^* n$  (Initial setup)
- (2) Take some  $m \in \mathbb{N}$  such that  $E \Downarrow m$  (By totality of  $\Downarrow$ )
- (3)  $n = m$  (By 1,2 & uniqueness of result for  $\rightarrow$ )
- (4)  $E \Downarrow n$  (By 3)

It is also possible to prove this without using normalisation and determinacy, by induction on  $E$ .

### 3.3.4 Multi-Step Reductions

#### Lemmas

$$\forall r \in \mathbb{N}. \forall E_1, E'_1, E_2. [E_1 \rightarrow^r E'_1 \Rightarrow (E_1 + E_2) \rightarrow^r (E'_1 + E_2)]$$

To prove  $\forall r \in \mathbb{N}. [P(r)]$  by induction on  $r$ :

#### Base Case

- Base case is  $r = 0$ .
- Prove that  $P(0)$  holds.

### Inductive Step

- Inductive Case is  $r = k + 1$  for arbitrary  $k \in \mathbb{N}$ .
- Inductive hypothesis is  $P(k)$ .
- Prove  $P(k + 1)$  using inductive hypothesis.

### Proof of the Lemma

By induction on  $r$ : **Base Case:** Take some arbitrary  $E_1, E'_1, E_2 \in SimpleExp$  such that  $E_1 \rightarrow^0 E'_1$ .

$$\begin{aligned} (1) \quad & E_1 = E'_1 && (\text{By definition of } \rightarrow^0) \\ (2) \quad & (E_1 + E_2) = (E'_1 + E_2) && (\text{By 1}) \\ (3) \quad & (E_1 + E_2) \rightarrow^0 (E'_1 + E_2) && (\text{By definition of } \rightarrow^0) \end{aligned}$$

**Inductive Step:** Take arbitrary  $k \in \mathbb{N}$  such that  $P(k)$

$$\begin{aligned} (1) \quad & \text{Take arbitrary } E_1, E'_1, E_2 \text{ such that } E_1 \rightarrow E'_1 && (\text{Initial setup}) \\ (2) \quad & \text{Take arbitrary } E''_1 \text{ such that } E''_1 \rightarrow E'_1 \\ (3) \quad & (E_1 + E_2) \rightarrow^k (E''_1 + E_2) && (\text{By 2 \& IH}) \\ (4) \quad & (E''_1 + E_2) \rightarrow (E'_1 + E_2) && (\text{By 2 \& rule S-LEFT}) \\ (5) \quad & (E_1 + E_2) \rightarrow^{k+1} (E'_1 + E_2) && (3,4, \text{definition of } \rightarrow^{k+1}) \end{aligned}$$

### 3.3.5 Determinacy of $\rightarrow$ for Exp

We extend simple expressions configurations of the form  $\langle E, s \rangle$ .

$$E \in Exp ::= n|x|E + E|\dots$$

Determinacy:

$$\forall E, E_1, E_2 \in Exp. \forall s, s_1, s_2 \in State. [\langle E, s \rangle \rightarrow \langle E_1, s_1 \rangle \wedge \langle E, s \rangle \rightarrow \langle E_2, s_2 \rangle \Rightarrow \langle E_1, s_1 \rangle = \langle E_2, s_2 \rangle]$$

We prove this using property  $P$ :

$$P(E, s) \triangleq \forall E_1, E_2 \in Exp. \forall s_1, s_2 \in State. [\langle E, s \rangle \rightarrow \langle E_1, s_1 \rangle \wedge \langle E, s \rangle \rightarrow \langle E_2, s_2 \rangle \Rightarrow \langle E_1, s_1 \rangle = \langle E_2, s_2 \rangle]$$

**Base Case:**  $E = x$

Take arbitrary  $n \in \mathbb{N}$  and  $s \in State$  to show  $P(n, s)$

$$\begin{aligned} (1) \quad & \text{take } E_1 \in Exp, s_1 \in State \text{ such that } \langle n, s \rangle \rightarrow \langle E_1, s_1 \rangle && (\text{Initial setup}) \\ (2) \quad & \text{take } E_2 \in Exp, s_2 \in State \text{ such that } \langle n, s \rangle \rightarrow \langle E_2, s_2 \rangle && (\text{Initial setup}) \\ (3) \quad & n = E_1 \wedge s = s_1 && (\text{By 1 \& inversion on definition of E.NUM}) \\ (4) \quad & n = E_2 \wedge s = s_2 && (\text{By 2 \& inversion on definition of E.NUM}) \\ (5) \quad & E_1 = E_2 \wedge s_1 = s_2 && (\text{By 3 \& 4}) \\ (6) \quad & \langle E_1, s_1 \rangle = \langle E_2, s_2 \rangle && (\text{By 5 \& definition of configurations}) \end{aligned}$$

**Base Case:**  $E = x$

Take arbitrary  $x \in Var$  and  $s \in State$  to show  $P(n, s)$

$$\begin{aligned} (1) \quad & \text{take } E_1 \in \mathbb{N}, s_1 \in State \text{ such that } \langle x, s \rangle \rightarrow \langle E_1, s_1 \rangle && (\text{Initial setup}) \\ (2) \quad & \text{take } E_2 \in \mathbb{N}, s_2 \in State \text{ such that } \langle x, s \rangle \rightarrow \langle E_2, s_2 \rangle && (\text{Initial setup}) \\ (3) \quad & E_1 = s(x) \wedge s_1 = s && (\text{By 1 \& inversion on definition of E.VAR}) \\ (3) \quad & E_2 = s(x) \wedge s_2 = s && (\text{By 2 \& inversion on definition of E.VAR}) \\ (5) \quad & E_1 = E_2 \wedge s_1 = s_2 && (\text{By 3 \& 4}) \\ (6) \quad & \langle E_1, s_1 \rangle = \langle E_2, s_2 \rangle && (\text{By 5 \& definition of configurations}) \end{aligned}$$

... Inductive Step ...

### 3.3.6 Syntax of Commands

$$C \in Com ::= x := E | \text{if } B \text{ then } C \text{ else } C | C; C | \text{skip} | \text{while } B \text{ do } C$$

**Determinacy**

$$\forall C, C_1, C_2 \in Com. \forall s, s_1, s_2 \in State. [\langle C, s \rangle \rightarrow_c \langle C_1, s_1 \rangle \wedge \langle C, s \rangle \rightarrow_c \langle C_2, s_2 \rangle \Rightarrow \langle C_1, s_1 \rangle = \langle C_2, s_2 \rangle]$$

## Confluence

$\forall C, C_1, C_2 \in Com. \forall s, s_1, s_2 \in State. [\langle C, s \rangle \rightarrow_c^* \langle C_1, s_1 \rangle \wedge \langle C, s \rangle \rightarrow_c^* \langle C_2, s_2 \rangle \Rightarrow \exists C' \in Com. \exists s' \in State. [\langle C_1, s_1 \rangle \rightarrow_c^* \langle C', s' \rangle \wedge \langle C_2, s_2 \rangle \rightarrow_c^* \langle C', s' \rangle]]$

## Unique Answer

$\forall C \in Com. \forall s_1, s_2 \in State. [\langle C, s \rangle \rightarrow_c^* \langle skip, s_1 \rangle \wedge \langle C, s \rangle \rightarrow_c^* \langle skip, s_2 \rangle \Rightarrow s_1 = s_2]$

## No Normalisation

There exist derivations of infinite length for while.

### 3.3.7 Connecting $\Downarrow$ and $\rightarrow^*$ for While

1.  $\forall E, n \in Exp. \forall s, s' \in State. [\langle E, s \rangle \Downarrow_e \langle n, s' \rangle \Leftrightarrow \langle E, s \rangle \rightarrow_e^* \langle n, s' \rangle]$
2.  $\forall B, b \in Bool. \forall s, s' \in State. [\langle B, s \rangle \Downarrow_b \langle b, s' \rangle \Leftrightarrow \langle B, s \rangle \rightarrow_b^* \langle b, s' \rangle]$
3.  $\forall C \in Com. \forall s, s' \in State. [\langle C, s \rangle \Downarrow_c \langle s' \rangle \Leftrightarrow \langle C, s \rangle \rightarrow_c^* \langle skip, s' \rangle]$

For  $Exp$  and  $Bool$  we have proofs by induction on the structure of expressions/booleans.

For  $\Downarrow_c$  it is more complex as the  $\Downarrow_c \Leftarrow \rightarrow_c^*$  cannot be proven using totality. Instead *complete/strong induction* on length of  $\rightarrow_c^*$  is used.

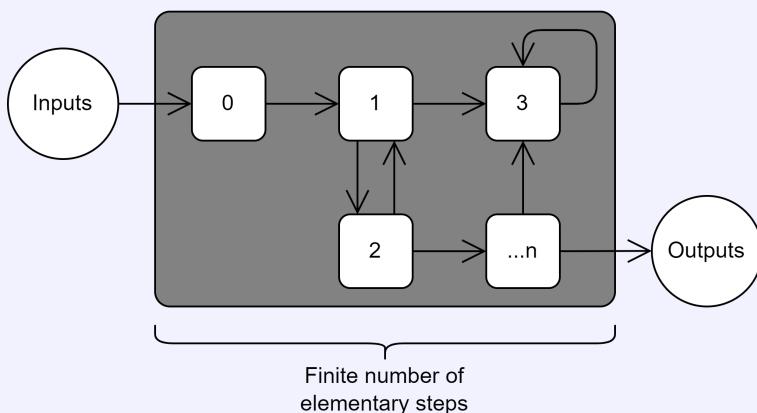

# Chapter 4

## Register Machines

### 4.1 Algorithms

Hilbert's Entscheidungsproblem (Decision Problem)	Definition 4.1.1
A problem proposed by David Hilbert and Wilhem Ackermann in 1928. Considering if there is an algorithm to determine if any statement is universally valid (valid in every structure satisfying the axioms - facts within the logic system assumed to be true (e.g in maths $1 + 0 = 1$ )).	
This can be also be expressed as an algorithm that can determine if any first-order logic statement is provable given some axioms.	
It was proven that no such algorithm exists by Alonzo Church and Alan Turing using their notions of Computing which show it is not computable.	

Algorithms Informally	Definition 4.1.2
One definition is: <i>A finite, ordered series of steps to solve a problem.</i>	
Common features of the many definitions of algorithms are:	
<b>Finite</b> <b>Deterministic</b> <b>Terminating?</b>	Finite number of elementary (cannot be broken down further) operations. Next step uniquely defined by the current. May not terminate, but we can see when it does & what the result is.

## 4.2 Register Machines

### Register Machine

### Definition 4.2.1

A turing-equivalent (same computational power as a turing machine) abstract machine that models what is computable.

- Infinitely many registers, each storing a natural number ( $\mathbb{N} \triangleq \{0, 1, 2, \dots\}$ )
- Each instruction has a label associated with it.

There are 3 instructions:

$R_i^+ \rightarrow L_m$	Add 1 to register $R_i$ and then jump to the instruction at $L_m$
$R_i^- \rightarrow L_n, L_m$	If $R_i > 0$ then decrement it and jump to $L_n$ , else jump to $L_m$
<b>HALT</b>	Halt the program.

At each point in a program the registers are in a configuration  $c = (l, r_0, \dots, r_n)$  (where  $r_i$  is the value of  $R_i$  and  $l$  is the instruction label  $L_l$  that is about to be run).

- $c_0$  is the initial configuration, next configurations are  $c_1, c_2, \dots$
- In a finite computation, the final configuration is the **halting configuration**.
- In a **proper halt** the program ends on a **HALT**.
- In an **erroneous halt** the program jumps to a non-existent instruction, the **halting configuration** is for the instruction immediately before this jump.

### Sum of three numbers

### Example Question 4.2.1

The following register machine computes:

$$R_0 = R_0 + R_1 + R_2 \quad R_1 = 0 \quad R_2 = 0$$

Or as a partial function:

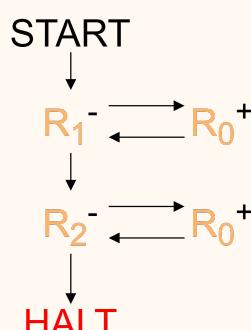

$$f(x, y, z) = x + y + z$$

#### Registers

$R_0 \quad R_1 \quad R_2$

#### Program

$L_0 : R_1^- \rightarrow L_1, L_2$   
 $L_1 : R_0^+ \rightarrow L_0$   
 $L_2 : R_2^- \rightarrow L_3, L_4$   
 $L_3 : R_0^+ \rightarrow L_2$   
 $L_4 : \text{HALT}$

#### Example Configuration

$L_i$	$R_0$	$R_1$	$R_2$
0	1	2	3
1	1	1	3
0	2	1	3
1	2	0	3
0	3	0	3
2	3	0	3
3	3	0	2
2	4	0	2
3	4	0	1
2	5	0	1
3	5	0	0
2	6	0	0
4	6	0	0

### 4.2.1 Partial Functions

#### Partial Function

#### Definition 4.2.2

Maps some members of the domain  $X$ , with each mapped member going to at most one member of the codomain  $Y$ .

$$f \subseteq X \times Y \text{ and } (x, y_1) \in f \wedge (x, y_2) \in f \Rightarrow y_1 = y_2$$

$f(x) = y$	$(x, y) \in f$
$f(x) \downarrow$	$\exists y \in Y. [f(x) = y]$
$f(x) \uparrow$	$\neg \exists y \in Y. [f(x) = y]$
$X \rightarrow Y$	Set of all <i>partial functions</i> from $X$ to $Y$ .
$X \rightarrow Y$	Set of all <i>total functions</i> from $X$ to $Y$ .

A partial function from  $X$  to  $Y$  is total if it satisfies  $f(x) \downarrow$ .

Register machines can be considered as partial functions as for a given input/initial configuration, they produce at most one halting configuration (as they are deterministic, for non-finite computations/non-halting there is no halting configuration).

We can consider a register machine as a partial function of the input configuration, to the value of the first register in the halting configuration.

$$f \in \mathbb{N}^n \rightarrow \mathbb{N} \text{ and } (r_0, \dots, r_n) \in \mathbb{N}^n, r_0 \in \mathbb{N}$$

Note: Many different register machines may compute the same partial function.

### 4.2.2 Computable Functions

The following arithmetic functions are computable. Using them we can derive larger register machines for more complex arithmetic (e.g. logarithms making use of repeated division).

#### Projection

$$p(x, y) \triangleq x$$

$$(r_0, r_1) \rightarrow r_0$$

HALT

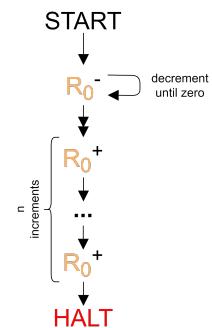

#### Constant

$$c(x) \triangleq n$$

$$(r_0) \rightarrow n$$

$$\begin{aligned} L_0 : & R_0^- \rightarrow L_0, L_1 \\ L_1 : & R_0^+ \rightarrow L_2 \\ \vdots & \vdots \\ L_n : & R_0^+ \rightarrow L_{n+1} \\ L_{n+1} : & \text{HALT} \end{aligned}$$

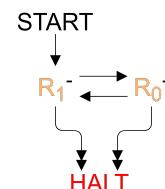

#### Truncated Subtraction

$$x - y \triangleq \begin{cases} x - y & y \leq x \\ 0 & y > x \end{cases}$$

$$(r_0, r_1) \rightarrow r_0 - r_1$$

$$\begin{aligned} L_0 : & R_1^- \rightarrow L_1, L_2 \\ L_1 : & R_0^- \rightarrow L_0, L_2 \\ L_2 : & \text{HALT} \end{aligned}$$

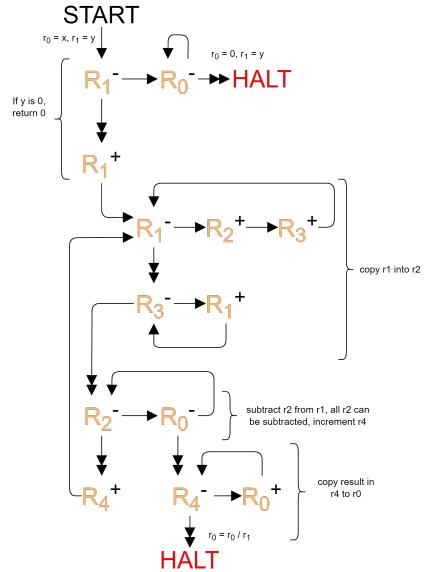

#### Integer Division

Note that this is an inefficient implementation (to make it easy to follow) we could combine the halts and shortcut the initial zero check (so we don't increment, then re-decrement).

$$x \text{ div } y \triangleq \begin{cases} \left\lfloor \frac{x}{y} \right\rfloor & y > 0 \\ 0 & y = 0 \end{cases}$$

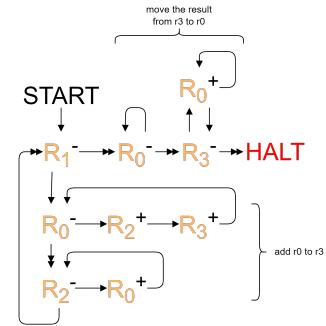

- $L_0 : R_1^- \rightarrow L_3, L_2$   
 $L_1 : R_0^- \rightarrow L_1, L_2$   
 $L_2 : \text{HALT}$   
 $L_3 : R_1^+ \rightarrow L_4$   
 $L_4 : R_1^- \rightarrow L_5, L_7$   
 $L_5 : R_2^+ \rightarrow L_6$   
 $L_6 : R_3^+ \rightarrow L_4$   
 $L_7 : R_3^- \rightarrow L_8, L_9$   
 $L_8 : R_1^+ \rightarrow L_9$   
 $L_9 : R_2^- \rightarrow L_{10}, L_4$   
 $L_{10} : R_0^- \rightarrow L_9, L_{11}$   
 $L_{11} : R_4^- \rightarrow L_{12}, L_{13}$   
 $L_{12} : R_0^+ \rightarrow L_{11}$   
 $L_{13} : \text{HALT}$

## Multiplication

$$x \times y$$

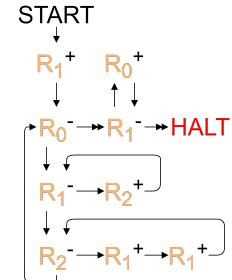

- $L_0 : R_1^- \rightarrow L_5, L_1$   
 $L_1 : R_0^- \rightarrow L_1, L_2$   
 $L_2 : R_3^- \rightarrow L_3, L_4$   
 $L_3 : R_0^+ \rightarrow L_2$   
 $L_4 : \text{HALT}$   
 $L_5 : R_0^- \rightarrow L_6, L_8$   
 $L_6 : R_2^+ \rightarrow L_7$   
 $L_7 : R_3^+ \rightarrow L_5$   
 $L_8 : R_2^- \rightarrow L_9, L_0$   
 $L_9 : R_0^+ \rightarrow L_8$

## Exponent of base 2

$$e(x) \triangleq 2^x$$

- $L_0 : R_1^+ \rightarrow L_1$   
 $L_1 : R_0^- \rightarrow L_5, L_2$   
 $L_2 : R_1^- \rightarrow L_3, L_4$   
 $L_3 : R_0^+ \rightarrow L_2$   
 $L_4 : \text{HALT}$   
 $L_5 : R_1^- \rightarrow L_6, L_7$   
 $L_6 : R_2^+ \rightarrow L_5$   
 $L_7 : R_2^- \rightarrow L_8, L_1$   
 $L_8 : R_1^+ \rightarrow L_9$   
 $L_9 : R_1^+ \rightarrow L_7$

## 4.3 Encoding Programs as Numbers

### Halting Problem

### Definition 4.3.1

Given a set  $S$  of pairs  $(A, D)$  where  $A$  is an algorithm and  $D$  is some input data  $A$  operates on  $(A(D))$ .

We want to create some algorithm  $H$  such that:

$$H(A, D) \triangleq \begin{cases} 1 & A(D) \downarrow \\ 0 & \text{otherwise} \end{cases}$$

Hence if  $A(D) \downarrow$  then  $A(D)$  eventually halts with some result.

We can use proof by contradiction to show no such algorithm  $H$  can exist.

Assume an algorithm  $H$  exists:

$$B(p) \triangleq \begin{cases} \text{halts} & H(p(p)) = 0 \quad (p(p) \text{ does not halt}) \\ \text{forever} & H(p(p)) = 1 \quad (p(p) \text{ halts}) \end{cases}$$

Hence using  $H$  on any  $B(p)$  we can determine if  $p(p)$  halts ( $H(B(p)) \Rightarrow \neg H(p(p))$ ).

Now we consider the case when  $p = B$ .

**$B(B)$  halts**      Hence  $B(B)$  does not halt. Contradiction!

**$B(B)$  does not halt**    Hence  $B(B)$  halts. Contradiction!

Hence by contradiction there is not such algorithm  $H$ .

In order to reason about programs consuming/running programs (as in the halting problem), we need a way to encode programs as data. Register machines use natural numbers as values for input, and hence we need a way to encode any register machine as a natural number.

### 4.3.1 Pairs

$$\begin{array}{lll} \langle\langle x, y \rangle\rangle & = 2^x(2y + 1) & y \ 1 \ 0_1 \dots 0_x \quad \text{Bijection between } \mathbb{N} \times \mathbb{N} \text{ and } \mathbb{N}^+ = \{n \in \mathbb{N} | n \neq 0\} \\ \langle x, y \rangle & = 2^x(2y + 1) - 1 & y \ 0 \ 1_1 \dots 1_x \quad \text{Bijection between } \mathbb{N} \times \mathbb{N} \text{ and } \mathbb{N} \end{array}$$

### 4.3.2 Lists

We can express lists and right-nested pairs.

$$[x_1, x_2, \dots, x_n] = x_1 : x_2 : \dots : x_n = (x_1, (x_2, (\dots, x_n) \dots))$$

We use zero to define the empty list, so must use a bijection that does not map to zero, hence we use the pair mapping  $\langle\langle x, y \rangle\rangle$ .

$$l : \begin{cases} {}^\frown \! \square \triangleq 0 \\ {}^\frown \! x_1 :: l_{inner} \triangleq \langle\langle x, {}^\frown \! l_{inner} \rangle\rangle \end{cases}$$

Hence:

$${}^\frown \! x_1, \dots, x_n \triangleq \langle\langle x_1, \langle\langle \dots, x_n \rangle\rangle \dots \rangle\rangle$$

### 4.3.3 Instructions

$$\begin{aligned} {}^\frown \! R_i^+ \rightarrow L_n \triangleq & \langle\langle 2i, n \rangle\rangle \\ {}^\frown \! R_i^- \rightarrow L_n, L_m \triangleq & \langle\langle 2i + 1, \langle n, m \rangle \rangle\rangle \\ {}^\frown \! \text{HALT} \triangleq & 0 \end{aligned}$$

### 4.3.4 Programs

Given some program:

$${}^\frown \! \left( \begin{array}{l} L_0 : instruction_0 \\ \vdots \\ L_n : instruction_n \end{array} \right) \triangleq {}^\frown \! [{}^\frown \! instruction_0, \dots, {}^\frown \! instruction_n] \triangleq$$

In order to simplify checking workings, a basic python script for running, encoding and decoding register machines is provided (also available in the notes repository).

- It is designed to be used in the python shell, to allow for easy manipulation, storing, etc of register machines, encoding/decoding results.
- It also produces latex to show step-by-step workings for calculations.

Have a go at making your own register machine encode/decode and simulation in your language of choice!

## 4.4 Gadgets

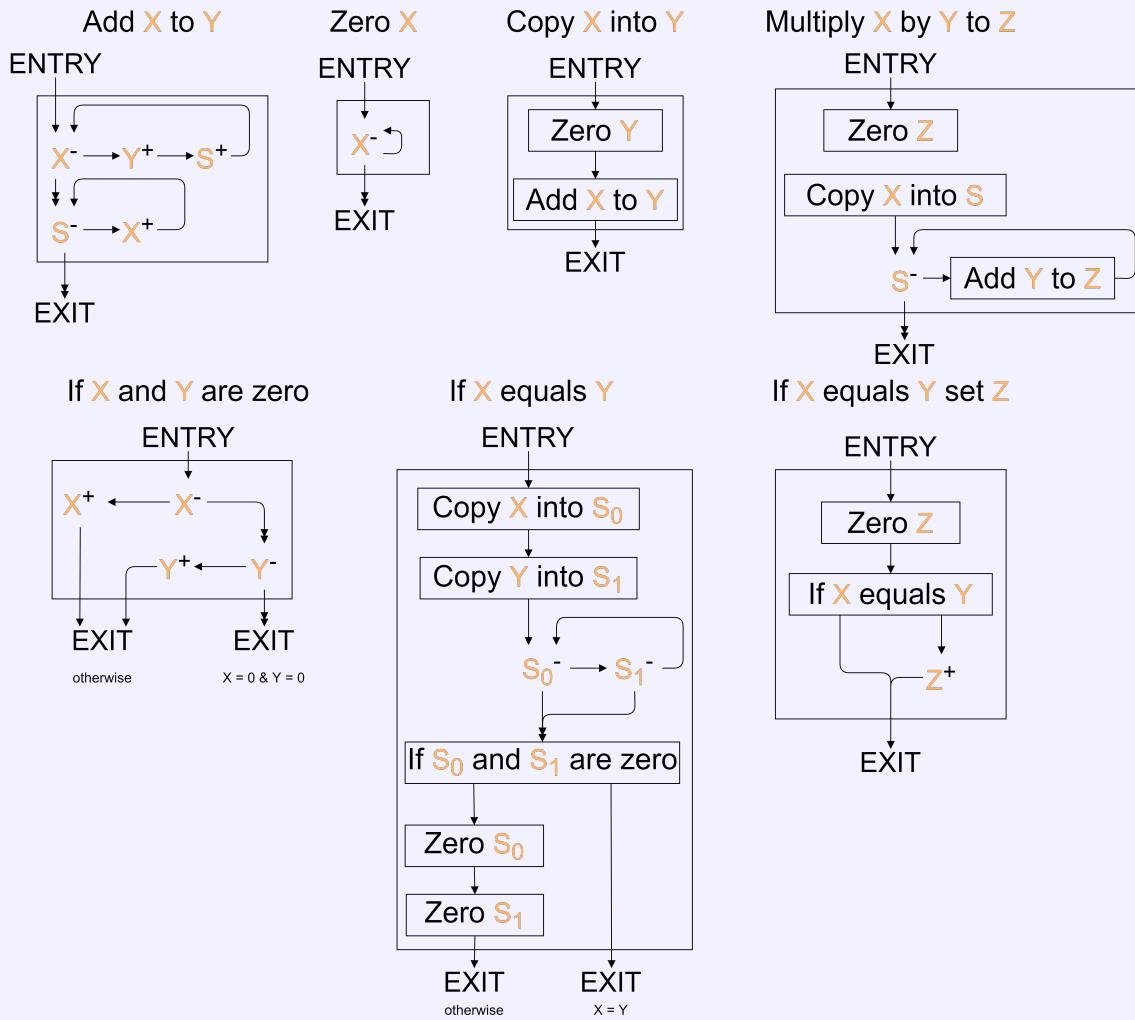

### Register Machine Gadget

### Definition 4.4.1

A gadget is a partial register machine graph, used as components in more complex programs, that can be composed into larger register machines or gadgets.

- Has a single *ENTRY* (much like *START*).
- Can have many *EXIT* (much like *HALT*).
- Operates on registers specified in the name of the gadget (e.g "Add  $R_1$  to  $R_2$ ").
- Can use scratch registers (assumed to be zero prior to gadget and set to zero by the gadget before it exits - allows usage in loops)
- We can rename the registers used in gadgets (simply change the registers used in the name (*push  $R_0$  to  $R_1$*   $\rightarrow$  *push  $X$  to  $Y$* ), and have all scratch registers renamed to registers unused by other parts of the program)

For example we can create several gadgets in terms of registers that we can rename.

And then can use these to create larger programs.

## 4.5 Analysing Register Machines

There is no general algorithm for determining the operations of a register machine (i.e halting problem)

However there are several useful strategies one can use:

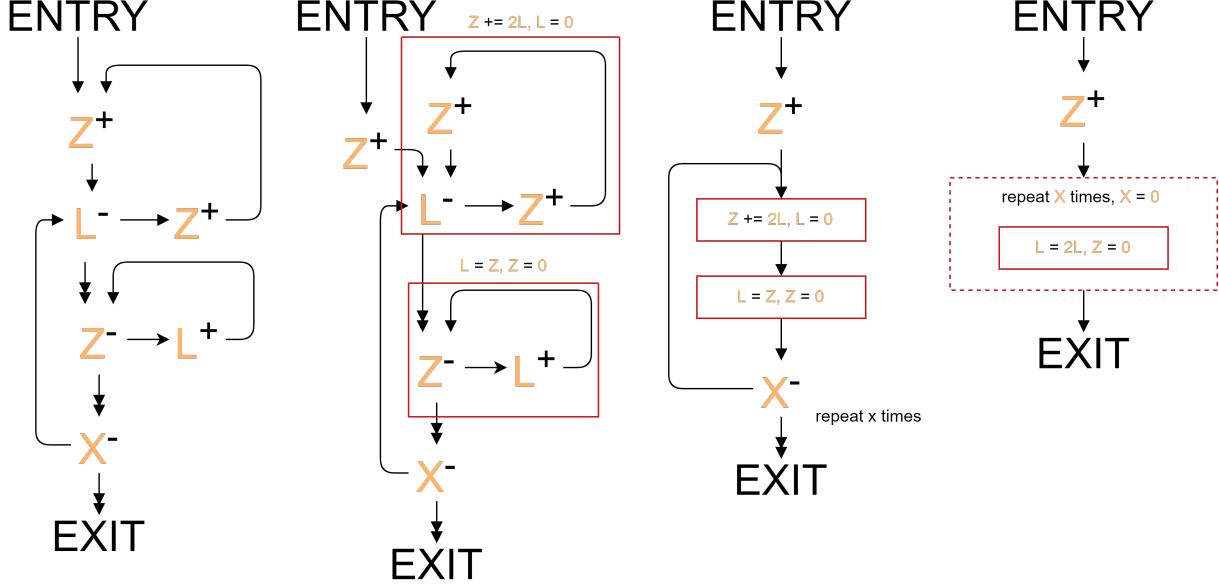

### 4.5.1 Experimentation

Can create a table of input values against outputs to attempt to determine the relation - however the values could match many different relations.

### 4.5.2 Creating Gadgets

We can group instructions together into gadgets to identify simple behaviours, and continue to merge to develop an understanding of the entire machine.

For example below, we can deduce the result as  $L = 2^X(2L + 1)$

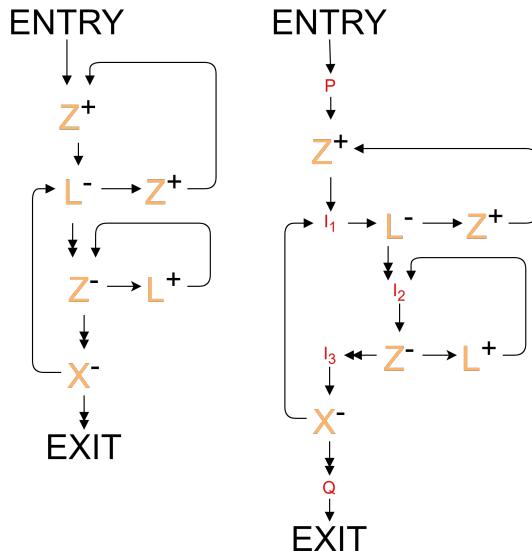

### 4.5.3 Invariants

We can use logical assertions on the register machine state at certain instructions, both to get the result of the register machine, and to prove the result.

If correct, every execution path to a given instruction's invariant, establishes that invariant.

We could attach invariants to every instruction, however it is usually only necessary to use them at the start, end and for loops (preconditions/postconditions).

Our first invariant ( $P$ ) can be defined as:

$$P \equiv (X = x \wedge L = l \wedge Z = 0)$$

Next we can use the instructions between invariant to find the states under which the invariants must hold.

<b>1.</b>	$P[Z - 1/Z] \Rightarrow I_1$	After incrementing $Z$ needs to go to the start of the first loop.
<b>2.</b>	$I_1[L + 1/L, Z - 2/Z] \Rightarrow I_1$	The loop decrements $L$ and increases $Z$ by two. After each loop iteration, $I_1$ must still hold.
<b>3.</b>	$I_1 \wedge L = 0 \Rightarrow I_2$	If $L = 0$ the loop is escaped, and we move to $I_2$ .
<b>4.</b>	$I_2[Z + 1/Z, L - 1/L] \Rightarrow I_2$	Loop increments $L$ and decrements $Z$ on each iteration, after this, $I_2$ must still hold.
<b>5.</b>	$I_2 \wedge Z = 0 \Rightarrow I_3$	Loop ends when $Z = 0$ , moves to $I_3$ .
<b>6.</b>	$I_3[X + 1/X] \Rightarrow I_1$	Large loop decrements $X$ on each iteration, invariant must hold with the new/decremented $X$ .
<b>7.</b>	$I_3 \wedge X = 0 \Rightarrow Q$	When the main $X$ -decrementing loop is escaped, we move to exit, so $Q$ must hold.

We can now use these constraints (also called *verification conditions*) to determine an invariant.

For each constraint we do:

1. Get the basic for (potentially one already derived) for the invariant in question.
2. If there is iteration, iterate to build up a disjunction.
3. Find the pattern, and then re-form the invariant based on it.

### Constraint 1.

Hence we can deduce  $I_1$  as:

$$I_1 = (X = x \wedge L = l \wedge Z = 1)$$

(Take  $P$  and increment  $Z$ )

### Constraint 2.

We can iterate to get the disjunction:

$$I_1 \equiv (X = x \wedge L = l \wedge Z = 1) \vee (X = x \wedge L + 1 = l \wedge Z - 2 = 1) \vee (X = x \wedge L + 2 = l \wedge Z - 4 = 1) \vee \dots$$

Hence we can determine the pattern for each disjunct as:

$$Z + 2L = 2l + 1$$

Hence we create our invariant:

$$I_1 = (X = x \wedge Z + 2L = 2l + 1)$$

### Constraint 3.

Hence as  $L = 0$  we can determine that  $Z = 2l + 1$ .

$$I_2 = (X = x \wedge Z = 2l + 1 \wedge L = 0)$$

### Constraint 4.

We iterate to get the disjunction:

$$I_2 = (X = x \wedge Z = 2l + 1 \wedge L = 0) \vee (X = x \wedge Z = 2l + 0 \wedge L = 1) \vee (X = x \wedge Z = 2l - 1 \wedge L = 2) \vee \dots$$

Hence we notice the pattern:

$$Z + L = 2l + 1$$

So can deduce the invariant:

$$I_2 = (X = x \wedge Z + L = 2l + 1)$$

### Constraint 5.

We can derive an invariant  $I_3$  using  $Z = 0$ .

$$I_3 = (X = x \wedge L = 2l + 1 \wedge Z = 0)$$

### Constraint 6.

We can use the constraint, and the currently derived  $I_1$  to get a disjunction:

$$I_1 = (X = x - 1 \wedge L = 2l + 1 \wedge Z = 0) \vee (X = x \wedge Z + 2L = 2l + 1)$$

We can apply constraint 2. on the first part of this disjunction, iterating to get the disjunction:

$$I_1 = (X = x \wedge Z + 2L = 2l + 1) \vee \left( \begin{array}{l} (X = x - 1 \wedge L = 2l + 1 \wedge Z = 0) \vee \\ (X = x - 1 \wedge L = 2l + 0 \wedge Z = 2) \vee \\ (X = x - 1 \wedge L = 2l - 1 \wedge Z = 4) \vee \\ (X = x - 1 \wedge L = 2l - 2 \wedge Z = 8) \vee \dots \end{array} \right)$$

Hence for the second group of disjuncts we have the relation:

$$Z + 2L = 2(2l + 1)$$

Hence we have:

$$I_1 = (X = x \wedge Z + 2L = 2l + 1) \vee (X = x - 1 \wedge Z + 2L = 2(2l + 1))$$

Hence when we repeat on the larger loop, we will double again, iterating we get:

$$I_1 = (X = x \wedge Z + 2L = 2l + 1) \vee (X = x - 1 \wedge Z + 2L = 2(2l + 1)) \vee (X = x - 2 \wedge Z + 2L = 4(2l + 1)) \vee \dots$$

Hence we have the relation:

$$I_1 = (Z + 2L = 2^{X-x}(2l + 1))$$

We can apply this doubling to  $L_2$  also as it forms part of the larger loop:

$$I_2 = (Z + L = 2^{X-x}(2l + 1))$$

And to  $I_3$ :

$$I_3 = (L = 2^{X-x}(2l + 1) \wedge Z = 0)$$

### Constraint 7.

Hence we can now derive  $Q$  as:

$$Q = (L = 2^x(2l + 1) \wedge Z = 0)$$

### Termination

We also need to show that each of our loops eventually terminate, we can do this by showing that some variant (e.g register, or combination of) decreases every time the invariant is reached/visited.

For  $I_1$  we can use the lexicographical ordering  $(X, L)$  as in each inner loop  $L$  decreases, but for the larger loop while  $L$  is reset/does not increase,  $X$  does.

For  $I_2$  we can similarly use the lexicographical ordering  $(X, Z)$

For  $I_3$  we can just use  $X$ .

## 4.6 Universal Register Machine

A register machine that simulates a register machine.

It takes the arguments:

$$\textcolor{red}{R}_0 = 0$$

$\textcolor{red}{R}_1$  = the program encoded as a number

$\textcolor{red}{R}_2$  = the argument list encoded as a number

All other registers zeroed

The registers used are:

$R_1$	P	Program code of the register machine being simulated/emulated.
$R_2$	A	Arguments provided to the simulated register machine.
$R_3$	PC	Program Counter - The current register machine instruction.
$R_4$	N	Next label number/next instruction to go to. Is also used to store the current instruction
$R_5$	C	The current instruction.
$R_6$	R	The value of the register used by the current instruction.
$R_7$	S	Auxiliary Register
$R_8$	T	Auxiliary Register
$R_9 \dots$		Scratch Registers

```

while true:
    if PC >= length P:
        HALT!

    N = P[PC]

    if N == 0:
        HALT!

    (curr, next) = decode(N)
    C = curr
    N = next

    # either C = 2i (R+) or C = 2i + 1 (R-)
    R = A[C // 2]

    # Execute C on data R, get next label and write back to registers
    (PC, R_new) = Execute(C, R)
    A[C//2] = R_new

```

# Chapter 5

## Halting Problem

### 5.1 Halting Problem for Register Machines

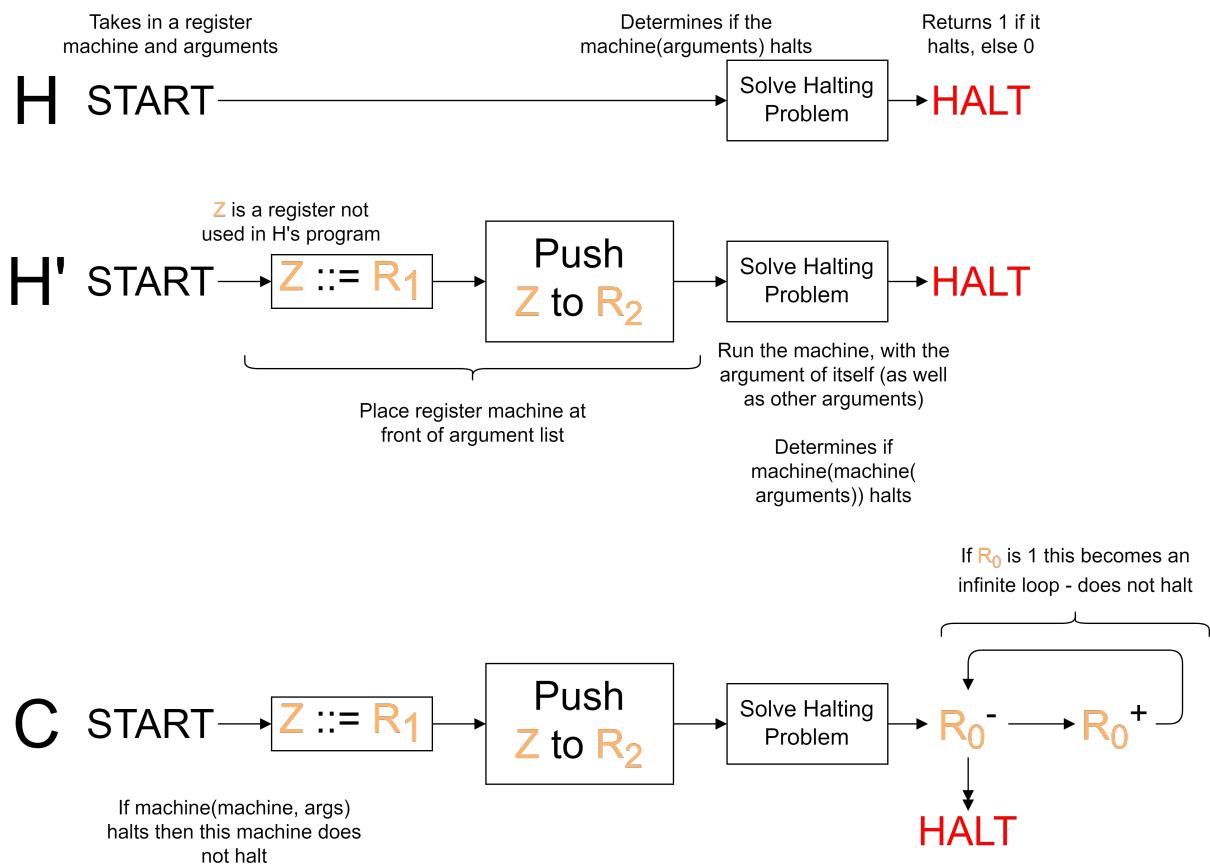

A register machine  $H$  decides the halting problem if for all  $e, a_1, \dots, a_n \in \mathbb{N}$ :

$$R_0 = 0 \quad R_1 = e \quad R_2 = \lceil [a_1, \dots, a_n] \rceil \quad R_{3..} = 0$$

And where  $H$  halt with the state as follows:

$$R_0 = \begin{cases} 1 & \text{Register machine encoded as } e \text{ halts when started with } R_0 = 0, R_1 = a_1, \dots, R_n = a_n \\ 0 & \text{otherwise} \end{cases}$$

We can prove that there is no such machine  $H$  through a contradiction.

Hence when we run  $C$  with the argument  $C$  we get a contradiction.

- |  |  |
|--|--|
| <b><math>C(C)</math> Halts</b>         | Then $C$ with $R_1 = \lceil C \rceil$ as an argument does not halt, which is a contradiction |
| <b><math>C(C)</math> Does not Halt</b> | Then $C$ with $R_1 = \lceil C \rceil$ as an argument halts, which is a contradiction         |

## 5.2 Computable Functions

### 5.2.1 Enumerating the Computable Functions

Onto (Surjective)	Definition 5.2.1
Each element in the codomain is mapped to by at least one element in the domain. $\forall y \in Y. \exists x \in X. [f(x) = y] \Rightarrow f \text{ is onto}$	

For each  $e \in \mathbb{N}$ ,  $\varphi_e \in \mathbb{N} \rightharpoonup \mathbb{N}$  (partial function computed by *program*( $e$ )):

$$\varphi_e(x) = y \Leftrightarrow \text{program}(e) \text{ with } R_0 = 0 \wedge R_1 = x \text{ halts with } R_0 = y$$

Hence for a given program  $\in \mathbb{N}$  we can get the computable partial function of the program.

$$e \mapsto \varphi_e$$

Therefore the above mapping represents an *onto/surjective* function from  $\mathbb{N}$  to all computable partial functions from  $\mathbb{N} \rightharpoonup \mathbb{N}$ .

### 5.2.2 Uncomputable Functions

For  $f : X \rightharpoonup Y$  (partial function from  $X$  to  $Y$ ):

$$\begin{aligned} f(x) \uparrow &\triangleq \neg \exists y \in Y. [f(x) = y] \\ f(x) \downarrow &\triangleq \exists y \in Y. [f(x) = y] \end{aligned}$$

Hence we can attempt to define a function to determine if a function halts.

$$f \in \mathbb{N} \rightharpoonup \mathbb{N} \triangleq \{(x, 0) | \varphi_x(x) \uparrow\} \triangleq f(x) = \begin{cases} 0 & \varphi_x(x) \uparrow \\ \text{undefined} & \varphi_x(x) \downarrow \end{cases}$$

However we run into the halting problem:

Assume  $f$  is computable, then  $f = \varphi_e$  for some  $e \in \mathbb{N}$ .

- if**  $\varphi_e(e) \uparrow$  by definition of  $f$ ,  $\varphi_e(e) = 0$  so  $\varphi_e(e) \downarrow$  which is a contradiction
- if**  $\varphi_e(e) \downarrow$  by definition of  $f$ ,  $f(e) \uparrow$ , and hence as  $f = \varphi_e$ ,  $\varphi_e \uparrow$  which is a contradiction

Here we have ended up with the halting problem being uncomputable.

### 5.2.3 Undecidable Set of Numbers

Given a set  $S \subseteq \mathbb{N}$ , its characteristic function is:

$$\chi_S \in \mathbb{N} \rightarrow \mathbb{N} \quad \chi_S(x) \triangleq \begin{cases} 1 & x \in S \\ 0 & x \notin S \end{cases}$$

$S$  is *register machine decidable* if its characteristic function is a register machine computable function.

$S$  is decidable iff there is a register machine  $M$  such that for all  $x \in \mathbb{N}$  when run with  $R_0 = 0, R_1 = x$  and  $R_{2..} = 0$  it eventually halts with:

$$R_0 = 1 \Leftrightarrow x \in S \quad R_0 = 0 \Leftrightarrow x \notin S$$

Hence we are effectively asking if a register machine exists that can determine if any number is in some set  $S$ .

We can then define subsets of  $\mathbb{N}$  that are decidable/undecidable.

#### The set of functions mapping 0 is undecidable

Given a set:

$$S_0 \triangleq \{e | \varphi_e(0) \downarrow\}$$

Hence we are finding the set of the indexes (numbers representing register machines) that halt on input 0.

If such a machine exists, we can use it to create a register machine to solve the halting problem. Hence this is a contradiction, so the set is undecidable.

**The set of total functions is undecidable**

Take set  $S_1 \subseteq \mathbb{N}$ :

$$S_1 \triangleq \{e \mid \varphi_e \text{ total function}\}$$

If such a register machine exists to compute  $\chi_{S_1}$ , we can create another register machine, simply checking 0. Hence as from the previous example, there is no register machine to determine  $S_0$ , there is none to determine  $S_1$ .

# Chapter 6

## Turing Machines

### 6.1 Definition

**Turing Machine**

**Definition 6.1.1**

Turing Machine  $\rightarrow M = (Q, \Sigma, s, \delta)$

Finite set of machine states  $s \in Q$   
Finite set of tape symbols  $\Sigma \triangleq \{\sqcup, 1, 0\}$   
Initial state  
transition function  $\delta \in (Q \times \Sigma) \rightharpoonup (Q \times \Sigma \times \{L, R\})$   
symbol at head (on tape) & current state  
symbol to write, new state, and move tape left or right

partial function (some symbols & states have no mapping)

$w \quad u$

$\sum \triangleq \{\sqcup, 1, 0\}$

Display the states and transitions as a mealy-machine diagram

current state  $= s$

tape head

Halt is encoded as jumping to an undefined state (configuration is normal form)

Symbol Read | Symbol to write { $\leftarrow, \rightarrow\right\}$

We can display the transition function as a table

$\sqcup$	1	0
$s$	$(q_1, 1, L)$	$(q_0, 1, R)$
$q_0$	$(q_0, 1, L)$	$(q_0, 1, L)$
$q_1$	$(q_1, 1, R)$	$(q_1, 0, L)$

No entry mean undefined, which results in a halt

Configuration:

Current State  $q \in Q$

left of tape head

right of tape head

$(q, w, u)$

finite string of symbols (possibly empty)  
 $w, u \in \Sigma^*$

Note: When matching on an empty list, we get a new, empty element

$\sqcup : [] = []$

$(q, w, u) \rightarrow_M (q', w', u')$

Transition moves to the left

$a : u' = u, b : w' = w, \delta(q, a) = (q', a', L)$

$(q, w, u) \rightarrow_M (q', w', b : a' : u')$

$w' \quad u'$

$b \quad a$

$q \quad q'$

Transition moves to the right

$a : u' = u, \delta(q, a) = (q', a', R)$

$(q, w, u) \rightarrow_M (q', w : a', u')$

$w \quad u'$

$a$

$q \quad q'$

$c_0 \rightarrow_M c_1 \rightarrow_M c_2 \rightarrow_M \dots \rightarrow_M \begin{cases} c_n & \text{finite sequence - the turing machine halts} \\ \dots & \text{infinite sequence - turing machine does not halt} \end{cases}$

*Register machines* abstract away the representation of numbers and operations on numbers (just uses  $\mathbb{N}$  with increment, decrement operations), *Turing machines* are a more concrete representation of computing.

### 6.1.1 Turing $\rightarrow$ Register Machine

We can show that any computation by a *Turing Machine* can be implemented by a *Register Machine*. Given a *Turing Machine*  $M$ :

1. Create a numerical encoding of  $M$ 's finite number of states, tape symbols, and initial tape contents.
2. Implement the transition table as a register machine.
3. Implement a register machine program to repeatedly carry out  $\rightarrow_M$

Hence *Turing Machine Computable*  $\Rightarrow$  *Register Machine Computable*.

#### Turing Machine Number Lists

In order to take arguments, and return value we need to encode lists on number on the tape of a turing machine. This is done as strings of unary values.

$$\text{Turing Machine Tape} = \{\sqcup, 0, 1\}^*$$

$\dots$      $0$      $1\dots 1$      $\sqcup$      $1\dots 1$      $\sqcup$      $\dots$      $\sqcup$      $1\dots 1$      $0$      $\dots$   
 all  $\sqcup$                $n_1$                $n_2$                $n_k$               all  $\sqcup$

#### Turing Computable

#### Definition 6.1.2

If  $f : \mathbb{N}^n \rightarrow \mathbb{N}$  is *Turing Computable* iff there is a turing machine  $M$  such that:

From initial state  $(s, \epsilon, [x_1, \dots, x_n])$  (tape head at the leftmost 0),  $M$  halts if and only if  $f(x_1, \dots, x_n) \downarrow$ , and halts with the tape containing a list, the first element of which is  $y$  such that  $f(x_1, \dots, x_n) = y$ .

More formally, given  $M = (Q, \Sigma, s, \delta)$  to compute  $f$ :

$$f(x_1, \dots, x_n) \downarrow \wedge f(x_1, \dots, x_n) = y \Leftrightarrow (s, \epsilon, [x_1, \dots, x_n]) \xrightarrow{*} M (*, \epsilon, [y, \dots])$$

#### Register $\rightarrow$ Turing Machine

It is also possible to simulate any register machine on a turing machine. As we can encode lists of numbers on the tape, we can simply implement the register machine operations as operations on integers on the tape.

Hence *Register Machine Computable*  $\Rightarrow$  *Turing Machine Computable*.

#### Notions of Computability

Every computable algorithm can be expressed as a turing machine (*Church-Turing Thesis*). In fact *Turing Machines*, *Register Machines* and the *Lambda Calculus* are all equivalent (all determine what is computable).

- **Partial Recursive Functions** Godel and Kleene (1936)
- **$\lambda$ -Calculus** Church (1936)
- **canonical systems for generating the theorems of a formal system** Post (1943) and Markov (1951)
- **Register Machines** Lambek and Minsky (1961)
- **And many more ...** (multi-tape turing machines, parallel computation, turing machines embedded in cellular automata etc)

# Chapter 7

## Lambda Calculus

Type Systems for Programming Languages

*Extra Fun! 7.0.1*

The third-year type systems module contains an introduction to lambda calculus that can be found here.

### 7.1 Lambda Calculus

	Variable	Abstraction	Application
$M ::=$	$x$	$\lambda x. M$	$M M$
	Left associative $((M) M) M$		

### 7.2 Syntax

<b>Bound Variables</b>	$x$ is bound inside $\lambda x . M$ (it is bound within the scope of $M$ )
<b>Free Variables</b>	$y$ is free inside $\lambda x . M$ (it is not bound)
<b>Closed Term</b>	A $\lambda$ -term with no free variables, e.g $\lambda x y z . x y$
<b>Binding Occurrences</b>	The $\lambda$ -term's parameters $\lambda x y z . (\dots)$ , here the $x$ , $y$ and $z$ before the dot.
<b>Left Associativity</b>	Lambda Terms are left associative, hence $A B C D \equiv (((A) (B)) (C)) (D)$

#### 7.2.1 Bound and Free Formally

$$\begin{aligned} \text{FreeVariables } (x) &= \{x\} \\ \text{FreeVariables } (\lambda x . M) &= \text{FreeVariables}(M) \setminus \{x\} \\ \text{FreeVariables } (M N) &= \text{FreeVariables}(M) \cup \text{FreeVariables}(N) \end{aligned}$$

$\alpha$ -equivalence

Definition 7.2.1

$M =_{\alpha} N$  if and only if  $N$  can be obtained from  $M$  by renaming bound variables (or vice-versa)

Hence the free variable set must be the same (not renamed).

#### 7.2.2 Substitution

$M[new/old]$  means replace free variable  $old$  with  $new$  in  $M$

Only free variables can be substituted. Formally we can describe this as:

$$x[M/y] = \begin{cases} M & x = y \\ x & x \neq y \end{cases}$$

$$(\lambda x . N)[M/y] = \begin{cases} \lambda x . N & x = y \text{ (x will be bound inside, so cannot go further)} \\ \lambda z . N[z/x][M/y] & x \neq y \text{ (To avoid name conflicts with } M, z \notin ((FV(N) \setminus \{x\}) \cup FV(M) \cup \{y\})) \end{cases}$$

$$(A B)[M/y] = (A[M/y]) (B[M/y])$$

- For variables, simply check if equal.
- For lambda abstractions, if the old term is bound, cannot go further, else, switch the bound term for some term not free inside, in the substitution, and not the new value replacing.
- For applications, simply substitute into both  $\lambda$ -terms.

Basic Substitution	Example Question 7.2.1
$x[y/x] = y$ $y[y/x] = y$ $(x y)[y/x] = y y$ $\lambda x . x y[y/x] = \lambda x . x y$	

## 7.3 Semantics

$$\frac{}{(\lambda x . M) N \rightarrow_{\beta} M[N/x]} \quad \frac{M \rightarrow_{\beta} M'}{\lambda x . M \rightarrow_{\beta} \lambda x . M'} \quad \frac{M \rightarrow_{\beta} M'}{M N \rightarrow_{\beta} M' N} \quad \frac{N \rightarrow_{\beta} N'}{M N \rightarrow_{\beta} M N'}$$

$$\frac{M =_{\alpha} M' \quad M' \rightarrow_{\beta} N' \quad N' =_{\alpha} N}{M \rightarrow_{\beta} N}$$

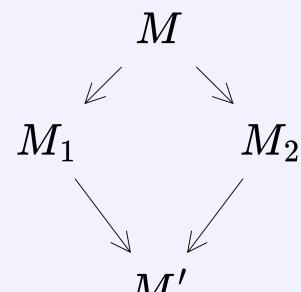

- A term of the form  $(\lambda x . N) M$  is called a *redex*.
- A  $\lambda$ -term may have several different reductions. These different reductions for a *derivation tree*.

### 7.3.1 Multi-Step Reductions

Steps can be combined using the transitive closure of  $\rightarrow_{\beta}$  under  $\alpha$ -conversion.

$$\frac{M =_{\alpha} M'}{M \rightarrow_{\beta}^* M'} \quad (\text{Reflexivity of } \alpha\text{-conversion})$$

$$\frac{M \rightarrow_{\beta} M' \quad M' \rightarrow_{\beta}^* M''}{M \rightarrow_{\beta}^* M''} \quad (\text{Transitivity})$$

Confluence	Definition 7.3.1
All derivation paths in the derivation tree that reach some normal form, reach the same normal form.	$\forall M, M_1, M_2. [M \rightarrow_{\beta}^* M_1 \wedge M \rightarrow_{\beta}^* M_2 \Rightarrow \exists M'. [M_1 \rightarrow_{\beta}^* M' \wedge M_2 \rightarrow_{\beta}^* M']]$ 

### $\beta$ Normal Forms

### Definition 7.3.2

A  $\lambda$ -term is in  $\beta$ -normal form if it contains no *redexes*, and hence cannot be further reduced.

$$\text{is in normal form}(M) \triangleq \forall N. M \not\rightarrow_{\beta} N$$

$$\text{has a normal form}(M) \triangleq \exists M'. M \rightarrow_{\beta}^* M' \wedge \text{is in normal form}(M')$$

If a normal form exists, it is unique.

$$\forall M, N_1, N_2. [M \rightarrow_{\beta}^* N_1 \wedge M \rightarrow_{\beta}^* N_2 \wedge \text{is-norm-form}(N_1) \wedge \text{is-norm-form}(N_2) \Rightarrow N_1 =_{\alpha} N_2]$$

### $\beta$ -equivalence

### Definition 7.3.3

An equivalence relation for  $\rightarrow_{\beta}$ .

$$M =_{\beta} N \Leftrightarrow \exists T. [M \rightarrow_{\beta}^* T \wedge N \rightarrow_{\beta}^* T]$$

## 7.3.2 Reduction Order

For a *redex*  $E = (\lambda x . M) N$ :

- Any *redex* in  $M$  or  $N$  is inside of  $E$
- $E$  is outside of any *redex* in  $M$  or  $N$

#### Innermost Redex

#### Definition 7.3.4

A *Redex* with no *redexes* inside of it.

#### Outermost Redex

#### Definition 7.3.5

A *Redex* with no *redexes* outside of it.

We can choose several different orders by which to reduce.

#### Normal Order

#### Definition 7.3.6

- Reduce the *leftmost outermost redex* first.
- This always reduces a  $\lambda$ -term to its normal form if one exists.
- Can perform computations on unevaluated function bodies.
- Not used in any programming languages.

#### Call By Name

#### Definition 7.3.7

- Reduce the *leftmost outermost* first.
- Does not reduce the inside of  $\lambda$ -abstractions.
- Does not always reduce a  $\lambda$ -term to its normal form.
- Passes unevaluated function parameters into function body. Only evaluating a parameter when it is used.
- Used with some variation by Haskell, R, and L<sup>A</sup>T<sub>E</sub>X.

#### Call By Values

#### Definition 7.3.8

- Reduce the *leftmost innermost redex* first.
- Does not reduce the inside of  $\lambda$ -abstractions.
- Does not always reduce a  $\lambda$ -term to its normal form.
- Evaluate parameters before passing them to function body.
- Terminates less often than *call by name* (e.g. if a parameter cannot be normalised, but is never used), but evaluated the parameters only once.
- Used by C, Rust, Java, etc.

Captures equality better than  $=_\beta$ .

$$\frac{x \notin FV(M)}{\lambda x . M \ x =_\eta M} \quad \frac{\forall N. M \ N =_{\eta^+} M' \ N}{M =_{\eta^+} M'}$$

Namely if the application of  $M$  to another  $\lambda$ -term is equivalent to  $M'$  applied to the same  $\lambda$ -terms then  $M$  and  $M'$  are equivalent.

For example with the basic application of  $f$ :

$$\lambda x . f \ x \neq_\beta f \quad \text{however} \quad (\lambda x . f \ x) \ M =_\beta f \ M \quad \text{and} \quad \lambda x . f \ x \neq_\eta f$$

### 7.3.3 Definability

Partial function  $f : \mathbb{N}^n \rightarrow \mathbb{N}$  is  $\lambda$ -definable if and only if there is a closed  $\lambda$ -term  $M$  where:

$$f(x_1, \dots, x_n) = y \Leftrightarrow M \ x_1 \dots x_n =_\beta y$$

And

$$f(x_1, \dots, x_n) \uparrow \Leftrightarrow M \ x_1 \dots x_n \text{ has no normal form}$$

$\lambda$ -definable specifies what can be computed by the lambda calculus, and is equivalent to *Register Machine Computable* or *Turing Machine Computable*.

## 7.4 Encoding Mathematics

### 7.4.1 Encoding Numbers

We represent natural numbers as *Church Numerals*. These are  $n$  repeated applications of some function  $f$ .

$$\underline{n} \triangleq \lambda f . \lambda x . \underbrace{f(\dots(f \ x)\dots)}_{n \text{ times}} \text{ with } n \text{ applications of } f$$

$$\begin{aligned} \underline{0} &\triangleq \lambda f . \lambda x . x \\ \underline{1} &\triangleq \lambda f . \lambda x . f \ x \\ \underline{2} &\triangleq \lambda f . \lambda x . f \ f \ x \\ \underline{3} &\triangleq \lambda f . \lambda x . f \ f \ f \ x \\ \underline{4} &\triangleq \lambda f . \lambda x . f \ f \ f \ f \ x \\ \underline{5} &\triangleq \lambda f . \lambda x . f \ f \ f \ f \ f \ x \\ &\vdots \end{aligned}$$

### 7.4.2 Encoding Addition

Addition is represented as a function application:

$$\begin{aligned} \underline{m} &= \lambda f . \lambda x . \underbrace{f(\dots(f \ x)\dots)}_{m \text{ times}} & \underline{n} &= \lambda f . \lambda x . \underbrace{f(\dots(f \ x)\dots)}_{n \text{ times}} \\ \underline{m+n} &\triangleq \underbrace{(\lambda m . \lambda n . \lambda f . \lambda x . m \ f \ (n \ f \ x))}_{+} \underline{m} \underline{n} \end{aligned}$$

By applying the functions, we have  $f$  applied  $m+n$  times, representing the Church Numeral  $\underline{m+n}$ .

### 7.4.3 Encoding Multiplication

$$\begin{aligned} \underline{m} &= \lambda f . \lambda x . \underbrace{f(\dots(f \ x)\dots)}_{m \text{ times}} & \underline{n} &= \lambda f . \lambda x . \underbrace{f(\dots(f \ x)\dots)}_{n \text{ times}} \\ \underline{m \times n} &\triangleq \underbrace{(\lambda m . \lambda n . \lambda f . m \ (n \ f))}_{\times} \underline{m} \underline{n} \end{aligned}$$

Each application of the  $f$  inside  $m$  is substituted for  $n$  applications of  $f$ , using the above  $\lambda$ -abstraction we get  $m \times n$  applications of  $f$ .

#### 7.4.4 Exponentiation

$$\begin{aligned}\underline{m} &= \lambda f . \lambda x . \underbrace{f(\dots(f\ x)\dots)}_{m \text{ times}} \quad \underline{n} = \lambda f . \lambda x . \underbrace{f(\dots(f\ x)\dots)}_{n \text{ times}} \\ \underline{m^n} &\triangleq \underbrace{(\lambda m . \lambda n . n\ m)}_{\text{exponential}} \underline{m} \underline{n}\end{aligned}$$

#### 7.4.5 Conditional

$$\begin{aligned}\underline{m} &= \lambda f . \lambda x . \underbrace{f(\dots(f\ x)\dots)}_{m \text{ times}} \\ \text{if } m = 0 \text{ then } x_1 \text{ else } x_2 &\triangleq \underbrace{(\lambda m . \lambda x_1 . \lambda x_2 . m (\lambda z . x_2) x_1)}_{\text{if zero}} \underline{m}\end{aligned}$$

If  $\underline{m} = \underline{0} = \lambda f . \lambda x . x$  then  $x$  is returned, which will be  $x_1$ .

If not zero, then the  $f$  applied returns  $x_2$ , so any number of applications of  $f$ , results in  $x_2$ .

#### 7.4.6 Successor

$$\underline{m} = \lambda f . \lambda x . \underbrace{f(\dots(f\ x)\dots)}_{m \text{ times}}$$

We simply take  $\underline{m}$  and apply  $f$  one more time

$$\underline{m+1} \triangleq \underbrace{(\lambda m . \lambda f . \lambda x . f (m\ f\ x))}_{\text{succ}} \underline{m}$$

#### 7.4.7 Pairs

We can encode pairs as a function, with a selector  $s$  function. Hence by supplying *first* or *second* as the selector, we can use the pair.

$$\begin{aligned}\textit{newpair}(a, b) &\triangleq \underbrace{(\lambda a . \lambda b . \lambda s . s\ a\ b)}_{\textit{newpair}} a\ b \equiv \underbrace{(\lambda a\ b\ s . s\ a\ b)}_{\textit{newpair}} a\ b \\ \textit{first}(p) &\triangleq p \underbrace{(\lambda x . \lambda y . x)}_{\textit{first}} \equiv p \underbrace{(\lambda x\ y . x)}_{\textit{first}} \\ \textit{second}(p) &\triangleq p \underbrace{(\lambda x . \lambda y . y)}_{\textit{second}} \equiv p \underbrace{(\lambda x\ y . y)}_{\textit{second}}\end{aligned}$$

#### 7.4.8 Predecessor

$$\underline{m} = \lambda f . \lambda x . \underbrace{f(\dots(f\ x)\dots)}_{m \text{ times}}$$

We cannot remove applications of  $f$ , however we can use a pair to count up until the successor is  $\underline{m}$ .

Hence we first need a function to get the next pair from the current:

$$\textit{transition } p \triangleq \underbrace{(\lambda n . \textit{newpair} (\textit{second} n) ((\textit{second} n) + 1))}_{\textit{transition function}} p$$

We can then simply run the transition  $n$  times on a pair starting by using  $f = \textit{transition}$  and  $x = \textit{newpair} \underline{0} \underline{0}$ .

$$\textit{pred}(n) \triangleq \begin{cases} 0 & n = 0 \\ n - 1 & \text{otherwise} \end{cases}$$

$$\textit{pred}(n) \triangleq \underbrace{(\lambda n . n\ \textit{transition} (\textit{newpair} \underline{0} \underline{0}) \textit{first})}_{\textit{predecessor}} n$$

A simpler definition of predecessor is:

$$\textit{pred}(n) \triangleq \underbrace{(\lambda n . \lambda f . \lambda x . n (\lambda g . \lambda h . h (g\ f)) (\lambda u . x) (\lambda u . u))}_{\textit{predecessor}} n$$

### 7.4.9 Subtraction

We can use the predecessor function for subtraction. By applying the predecessor function  $\underline{n}$  times on some number  $\underline{m}$  we get  $\underline{m} - \underline{n}$ .

$$\underline{m} - \underline{n} \triangleq \underbrace{(\lambda m . \lambda n . m \text{ pred } n)}_{\text{subtract}} \underline{m} \underline{n}$$

## 7.5 Combinators

Combinator	Definition 7.5.1
A closed $\lambda$ -term (no free variables), usually denoted by capital letters that describe	

$$\begin{array}{ll}
 I \triangleq \lambda x . x & I(x) \triangleq x \\
 K \triangleq \lambda x y . x & K(x, y) \triangleq x \\
 S \triangleq \lambda x y z . x z (y z) & S(x, y, z) \triangleq x(z)(y(z)) \\
 T \triangleq \lambda x y . y x & T(x, y) \triangleq y(x) \\
 C \triangleq \lambda x y z . x z y & C(x, y, z) \triangleq x(z)(y) \\
 V \triangleq \lambda x y z . z x y & V(x, y, z) \triangleq z(x)(y) \\
 B \triangleq \lambda x y z . x (y z) & B(x, y, z) \triangleq x(y(z)) \\
 B' \triangleq \lambda x y z . y (x z) & B'(x, y, z) \triangleq y(x(z)) \\
 W \triangleq \lambda x y . x y y & W(x, y) \triangleq x(y)(y) \\
 Y \triangleq \lambda g . (\lambda x . g (x x)) (\lambda x . g (x x)) & Y(f) \triangleq (\lambda x \rightarrow f(x(x))) (\lambda x \rightarrow f(x(x)))
 \end{array}$$

Only  $SKI$  are required to define any *computable function* (can remove even  $\lambda$ -abstraction, this is called *SKI-Combinator Calculus*).

The  $Y$ -Combinator is used for recursion. In one step of  $\beta$ -reduction:

$$Y f \rightarrow_{\beta} f (Y f)$$

We cannot define  $\lambda$ -terms in terms of themselves, as the  $\lambda$ -term is not yet defined, and infinitely large  $\lambda$ -terms are not allowed.

We can use the  $Y$ -Combinator to create recursion in the absence of recursive  $\lambda$ -term definitions.

Fixed-Point Combinator	Definition 7.5.2
A higher order function (e.g $fix$ ) that returns some function of itself: $fix f = f(fix f)$ $fix f = f(f(\dots f(fix f) \dots))$ (after repeated application)	

Factorial	Example Question 7.5.1
	$fact(n) = \begin{cases} 1 & n = 0 \\ n \times fact(n - 1) & \text{otherwise} \end{cases}$ <p>If recursive definitions for <math>\lambda</math>-terms were allowed, we could express this as:</p> $  \begin{aligned}  fact &\triangleq \lambda n . \text{if zero } n \perp \text{(multiply } n \text{ (fact (pred } n))) \\  &\triangleq (\lambda f . \lambda n . \text{if zero } n \perp \text{(multiply } n \text{ (f (pred } n)))) \text{ fact}  \end{aligned}  $ <p>Since we can use the above form (higher order function applied to itself) with the <math>Y</math> combinator.</p> $fact \triangleq Y(\lambda f . \lambda n . \text{if zero } n \perp \text{(multiply } n \text{ (f (pred } n))))$
